RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are :—

Canadian Journal of Biochemistry and Physiology	Bi-monthly	$3.00
Canadian Journal of Botany	Bi-monthly	$4.00
Canadian Journal of Chemistry	Monthly	$5.00
Canadian Journal of Microbiology . . .	Bi-monthly	$3.00
Canadian Journal of Physics	Monthly	$4.00
Canadian Journal of Technology	Bi-monthly	$3.00
Canadian Journal of Zoology	Bi-monthly	$3.00

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa 2, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 10, No. 1, 1956. 35s. net

E. M. HUME. Obituary notice (Charles James Martin, Kt.).

J. T. IRVING and MARION B. RICHARDS. The protective action of vitamin A upon various tissues in the avitaminotic rat and the sensitivity of these tissues to vitamin A deficiency.

ELIZABETH J. CASTLE. The rate of passage of foodstuffs through the alimentary tract of the goat. Studies on adult animals fed on hay and concentrates.

M. S. MAMEESH, H. E. SCHENDEL, H. W. NORTON and B. CONNOR JOHNSON. The effect of penicillin on the thiamine requirement of the rat.

B. M. CHURCH and S. LIPTON. The use of an electronic computer in the estimation of sampling errors in a nutritional survey.

E. AAES-JØRGENSEN, J. P. FUNCH, P. F. ENGEL and H. DAM. The role of fat in the diet of rats. 8. Influence on growth of shortenings, 'emulsifier PT 006' and polymerized linseed oil.

KATHLEEN M. HENRY and S. K. KON. Vitamin B_{12} and protein metabolism.

E. KODICEK, R. BRAUDE, S. K. KON and K. G. MITCHELL. The effect of alkaline hydrolysis of maize on the availability of its nicotinic acid to the pig.

Published for The Nutrition Society by the **Cambridge University Press, Bentley House, 200 Euston Road, N.W.1.** The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of The Nutrition Society* (2 parts a year) is £7. Single issues of either publication are 35s. each, plus postage.

Zentralblatt für Veterinärmedizin

Edited by

Prof. Dr. M. LERCHE
Free University, Berlin

and

Prof. Dr. H. SPÖRRI
University, Zürich

with the collaboration of many scientists of international repute

The *Zentralblatt für Veterinärmedizin* is an international journal which publishes the results of research in all branches of veterinary medicine. The journal provides the several disciplines of veterinary medicine with information on current aims and results in all the fields of research; it offers the information also to allied sciences so that a fruitful interchange of knowledge and ideas may develop.

Original papers appear in German, English, French or Spanish with summaries in all four languages.

In scope and volume the *Zentralblatt* exceeds other journals of veterinary medicine and in the presentation and value of the papers published is comparable with the best journals serving other sciences.

There are annually 6 parts each of 6 or 7 sheets. The parts of one calendar year form a volume.
Price per sheet (16 pages) about DM. 3. Each part is priced separately.

Zeitschrift für Tierzüchtung und Züchtungsbiologie

Founded in 1924 by C. KRONACHER]

Edited by Prof. Dr. J. SCHMIDT
with the collaboration of many international authorities

This journal is the recognised international organ for research on all branches of animal breeding, the biology of animal production and related subjects: racial biology, evolution, genetics, development, growth, constitution and adaptation; osteology and the mechanics of the skeleton, animal nutrition and animal hygiene.

It provides for all technical experts, veterinary officers and biologists a valuable survey of current research.

There are annually about 6 parts and 4 parts are a volume. A part is of about 6 sheets.
Price per sheet of 16 pages about DM. 4. Each part is separately priced.

Published by PAUL PAREY, Lindenstr. 44/47, Berlin, S.W.68 (Westberlin)

VETERINARY REVIEWS AND ANNOTATIONS

(First published April, 1955)

This NEW journal consists of reviews of topical subjects written by prominent workers. The reviews give up-to-date and critical summaries of the state of knowledge on their respective subjects and are designed to be of value not only to research workers but to workers in the field and in practice.

Contributions to Part I of Vol. 2, to be published in April, 1956, are

L. K. WHITTEN. The treatment of tapeworm infestations in man and animals.

CECIL A. HOARE. Toxoplasmosis in animals.

K. L. BLAXTER and ROSEMARY F. MCGILL. Magnesium metabolism in cattle.

I. G. MCINTOSH. Lead poisoning in animals.

LIST OF JOURNALS SCRUTINISED

(Arranged alphabetically according to Contracted Title)

Title of Journal	*Contracted Title*	*Last Number Scrutinised*	*Place of Publication*
Acta Agralia Fennica	Acta agral. fenn.	1955, **84,** No. 1	Helsinki, Finland
Acta Agriculturae Scandinavica	Acta Agric. scand.	1955, **5,** No. 3	Stockholm, Sweden
Acta Agronomica	Acta agronom., Colombia	1955, **5,** No. 2	Palmira, Colombia, South America
Acta Biologica Hungarica	Acta biol. hung.	1955, **6,** No. 1/2	Budapest, Hungary
Acta Chemica Scandinavica	Acta chem. scand.	1955, **9,** No. 5	Copenhagen, Denmark
Acta Chimica Hungarica	Acta chim. hung.	1955, **6,** No. 1/2	Budapest, Hungary
Acta Cientifica Venezolana	Acta cientif. venezol.	1954, **5,** No. 6	Caracas, Venezuela
Acta Gastro-Enterologica Belgica	Acta gastro-enterol. belg.	1955, **18,** No. 7/8	Brussels, Belgium
Acta Gerontologica	Acta gerontol.	1955, **5,** No. 4	Milan, Italy
Acta Leidensia	Acta leidensia	1954, **24**	Leyden, Holland
Acta Medica et Biologica	Acta med. biol.	1954, **2,** No. 2	Niigata, Japan
Acta Medica Hungarica	Acta med. hung.	1955, **6,** No. 3/4	Budapest, Hungary
Acta Medica Jugoslavica	Acta med. jugoslav.	1954, **8,** No. 3	Belgrade, Jugoslavia
Acta Medica Philippina	Acta med. philipp.	1953, **10,** No. 2	Manila, Philippines
Acta Medica Scandinavica	Acta med. scand.	1955, **152,** No. 2	Stockholm, Sweden
Acta Paediatrica	Acta paediat.	1955, **14,** No. 4	Stockholm, Sweden
Acta Paediatrica Belgica	Acta paediat. belg.	1955, **9,** No. 1	Brussels, Belgium
Acta Pathologica et Microbiologica Scandinavica	Acta pathol. microbiol. scand.	1955, **37,** No. 2	Copenhagen, Denmark
Acta Physiologica Hungarica	Acta physiol. hung.	1954, **6,** No. 4	Budapest, Hungary
Acta Physiologica Latino Americana	Acta physiol. Latino Amer.	1955, **4,** No. 1	Buenos Aires, Argentina
Acta Physiologica et Pharmacologica Neerlandica	Acta physiol. pharmacol. neerl.	1955, **4,** No. 1	Amsterdam, Holland
Acta Physiologica Scandinavica	Acta physiol. scand.	1955, **33,** No. 4	Stockholm, Sweden
Acta Radiologica	Acta radiol.	1955, **44,** No. 1	Stockholm, Sweden
Acta Scholae Medicinalis in Kioto	Acta Scholae med. Univ. Kioto	1955, **32,** No. 3	Kioto, Japan
Acta Societatis Medicorum Upsaliensis	Acta Soc. Med. upsalien.	1955, **60,** No. 1/2	Upsala, Sweden
Acta Veterinaria	Acta vet., Belgrade	1955, **5,** No. 2	Belgrade, Jugoslavia
Acta Vitaminologica	Acta vitaminol.	1955, **9,** No. 3	Milan, Italy
Advances in Biological and Medical Physics	Advances in Biol. Med. Phys.	1953, **3**	New York, U.S.A.
Advances in Carbohydrate Chemistry	Advances in Carbohydrate Chem.	1953, **8**	New York, U.S.A.
Advances in Enzymology	Advances in Enzymol.	1955, **16**	New York, U.S.A.
Advances in Food Research	Advances in Food Res.	1954, **5**	New York, U.S.A.
Advances in Protein Chemistry	Advances in Protein Chem.	1954, **9**	New York, U.S.A.
Advances in Veterinary Science	Advances in Vet. Sci.	1953, **1**	London, England
Agricultural Engineering	Agric. Eng.	1955, **36,** No. 8	St. Joseph, Mich., U.S.A.
Agricultural Gazette of New South Wales	Agric. Gaz. N.S.W.	1955, **66,** No. 5	Sydney, Australia
Agricultural Institute Review, Canada	Agric. Inst. Rev., Canada	1955, **1,** No. 4	Ottawa, Canada
Agricultural Review, The	Agric. Rev.	1955, **1,** No. 5	London, England
Agriculture, Journal of the Ministry of Agriculture	Agriculture, J. Minist. Agric. Engl.	1955, **62,** No. 6	London, England
Agrobiologiya	Agrobiologiya	1955, No. 1	Moscow, U.S.S.R.
Agronomy Journal	Agronom. J.	1955, **47,** No. 8	Washington, D.C., U.S.A.
Agronomia Lusitana	Agronom. lusitana	1954, **16,** No. 2	Alcobaca, Portugal
Akusherstvo i Ginekologiya	Akusherstvo Ginekol.	1955, No. 2	Moscow, U.S.S.R.
American Economic Review	Amer. Econ. Rev.	1955, **45,** No. 3	Menasha, Wis., U.S.A.
American Heart Journal	Amer. Heart J.	1955, **50,** No. 3	St. Louis, Mo., U.S.A.
American Journal of Anatomy	Amer. J. Anat.	1955, **96,** No. 2	Philadelphia, Pa., U.S.A.
American Journal of Clinical Nutrition	Amer. J. Clin. Nutrition	1955, **3,** No. 4	Allentown, Pa., U.S.A.
American Journal of Digestive Diseases	Amer. J. Digest. Dis.	1955, **22,** No. 8	Fort Wayne, Ind., U.S.A.
American Journal of Diseases of Children	Amer. J. Dis. Child.	1955, **90,** No. 2	Chicago, Ill, U.S.A.
American Journal of Medicine	Amer. J. Med.	1955, **19,** No. 2	New York, U.S.A.
American Journal of Medical Sciences	Amer. J. Med. Sci.	1955, **230,** No. 2	Philadelphia, Pa., U.S.A.
American Journal of Obstetrics and Gynecology	Amer. J. Obstet. Gynecol.	1955, **70,** No. 3	St. Louis, Mo., U.S.A.
American Journal of Ophthalmology	Amer. J. Ophthalmol.	1955, **39,** No. 3	Menasha, Wis., U.S.A.
American Journal of Orthopsychiatry	Amer. J. Orthopsychiat.	1955, **25,** No. 3	Menasha, Wis., U.S.A.
American Journal of Pathology	Amer. J. Pathol.	1955, **31,** No. 4	Ann Arbor, Mich., U.S.A.
American Journal of Physical Anthropology	Amer. J. Phys. Anthropol.	1955, **13,** No. 1	Philadelphia, Pa., U.S.A
American Journal of Physiology	Amer. J. Physiol.	1955, **181,** No. 3	Baltimore, Md., U.S.A.
American Journal of Surgery	Amer. J. Surg.	1955, **90,** No. 3	New York, U.S.A.

Title of Journal	*Contracted Title*	*Last Number Scrutinised*	*Place of Publication*
American Journal of Veterinary Research	Amer. J. Vet. Res.	1955, **16,** No. 60	Chicago, Ill., U.S.A.
Anais do Instituto de Medicina Tropical	An. Inst. Med. trop.	1955, **12,** No. 1/2	Lisbon, Portugal
Anales Instituto Nacional de Investigaciones Agronomicas Madrid	An. Inst. Nac. Invest. Agron. Madrid	1954, **3,** No. 4	Madrid, Spain
Analytical Chemistry	Anal. Chem.	1955, **27,** No. 9	Washington, D.C., U.S.A.
Analytica Chimica Acta	Anal. chim. Acta	1955, **13,** No. 3	Amsterdam, Holland
Analyst	Analyst	1955, **80,** No. 954	London, England
Anatomical Record	Anat. Rec.	1955, **122,** No. 1	Philadelphia, Pa., U.S.A.
Angewandte Chemie	Angew. Chem.	1955, **67,** No. 19/20	Weinheim, Germany
Annales de l'Institut National de la Recherche Agronomique. A. Annales Agronomiques	Ann. agronom.	1955, **6,** No. 3	Paris, France
Annals of Applied Biology	Ann. Appl. Biol.	1955, **43,** No. 2	Cambridge, England
Annales de Chimie	Ann. Chim., Paris	1955, **10,** June	Paris, France
Annals of Human Genetics	Ann. Human Genetics	1955, **20,** No. 1	London, England
Annales de l'Institut Pasteur	Ann. Inst. Pasteur	1955, **89,** No. 2	Paris, France
Annals of Internal Medicine	Ann. Int. Med.	1955, **43,** No. 2	Ann Arbor, Mich., U.S.A.
Annales Medicinae Experimentalis et Biologiae Fenniae	Ann. Med. exp. Biol. Fenn.	1955, **33,** No. 2	Helsinki, Finland
Annales Medicinae Internae Fenniae	Ann. Med. int. Fenn.	1955, **44,** No. 1	Helsinki, Finland
Annales de la Nutrition et de l'Alimentation	Ann. Nutrit. Alimentation	1955, **9,** No. 3	Paris, France
Annales d'Oculistique	Ann. Oculist.	1955, **188,** No. 8	Paris, France
Annals of Otology, Rhinology and Laryngology	Ann. Otol. Rhinol. Laryngol.	1955, **64,** No. 2	St. Louis, Mo., U.S.A.
Annales Paediatrici	Ann. paediat.	1955, **185,** No. 3	Basle, Switzerland
Annales Paediatriae Fenniae	Ann. Paediat. Fenn.	1954–55, **1,** No. 3	Helsinki, Finland
Annales de Parasitologie Humaine et Comparée	Ann. Parasitol.	1955, **30,** No. 4	Paris, France
Annales Pharmaceutiques Françaises	Ann. pharm. franç.	1955, **13,** May	Paris, France
Annals of Science	Ann. Sci.	1954, **10,** No. 4	London, England
Annales de la Société Belge de Médecine Tropicale	Ann. Soc. belg. Méd. trop.	1955, **35,** No. 1	Brussels, Belgium
Annali della Sperimentazione Agraria	Ann. Sper. agrar.	1954, **8,** No. 6	Rome, Italy
Annals of Surgery	Ann. Surg.	1955, **142,** No. 2	Philadelphia, Pa., U.S.A.
Annals of Tropical Medicine and Parasitology	Ann. Trop. Med. Parasitol.	1955, **49,** No. 2	Liverpool, England
Annales de l'Institut National de la Recherche Agronomique. S. D. Annales de Zootechnie	Ann. Zootech.	1955, **4,** No. 1	Paris, France
Annual Review of Biochemistry	Annu. Rev. Biochem.	1955, **24**	Stanford, Calif., U.S.A.
Annual Review of Medicine	Annu. Rev. Med.	1955, **6**	Stanford, Calif., U.S.A.
Annual Review of Microbiology	Annu. Rev. Microbiol.	1954, **8**	Stanford, Calif., U.S.A.
Annual Review of Physiology	Annu. Rev. Physiol.	1955, **17**	Stanford, Calif., U.S.A.
Antiseptic	Antiseptic	1955, **52,** No. 8	Madras, India
Antonie van Leeuwenhoek Journal of Microbiologie and Serology	Antonie van Leeuwenhoek J. Microbiol. Serol.	1955, **21,** No. 1	Amsterdam, Holland
Applied Statistics. A Journal of the Royal Statistical Society	Appl. Statistics	1955, **4,** No. 2	London, England
Archives of Biochemistry and Biophysics	Arch. Biochem. Biophys.	1955, **57,** No. 2	New York, U.S.A.
Archives of Disease in Childhood	Arch. Dis. Childhood	1955, **30,** No. 152	London, England
Naunyn-Schmiedebergs Archiv für Experimentelle Pathologie und Pharmakologie	Arch. exp. Pathol. Pharmakol.	1955, **226,** No. 3	Berlin : Göttingen : Heidelberg, Germany
Archivio di Fisiologia	Arch. Fisiol.	1954, **54,** No. 4	Florence, Italy
Archiv für Geflügelkunde	Arch. Geflugelk.	1955, **19,** No. 9/10	Stuttgart : Berlin, Germany
Archiv für Geschwulstforschung	Arch. Geschwulstforsch.	1955, **8,** No. 1	Dresden : Leipzig, Germany
Archiv für Gynäkologie	Arch. Gynäkol.	1955, **186**	Munich, Germany
Archiv. für Hygiene und Bakteriologie	Arch. Hyg., Berlin	1955, **139,** No. 2	Munich : Berlin, Germany
Archives of Industrial Health	Arch. Indust. Health	1955, **12,** No. 1	Chicago, Ill., U.S.A.
Archives de l'Institut Pasteur d'Algérie	Arch. Inst. Pasteur Algérie	1955, **33,** No. 2	Algiers, Algeria
Archives of Internal Medicine	Arch. Int. Med.	1955, **96,** No. 2	Chicago, Ill., U.S.A.
Archives Internationales de Pharmacodynamie et de Thérapie	Arch. internat. Pharmacodyn.	1955, **102,** No. 4	Ghent, Belgium
Archives Internationales de Physiologie	Arch. internat. Physiol.	1955, **63,** No. 2	Liège, Belgium
Archivio Italiano delle Malattie dell' Apparato Digerente	Arch. ital. Malat. Appar. diger.	1955, **21,** No. 4	Bologna, Italy
Archivio Italiano di Pediatria e Puericoltura	Arch. ital. Pediat. Puericolt.	1955, **17,** No. 4	Bologna, Italy
Archives des Maladies de l'Appareil Digestif et des Maiadies de la Nutrition	Arch. Mal. Appar. digest.	1955, **44,** No. 4	Paris, France
Archiva Medica Belgica	Arch. med. belg.	1955, **10,** No. 2	Brussels, Belgium
Archives of Neurology and Psychiatry	Arch. Neurol. Psychiat., Chicago	1955, **73,** No. 4	Chicago, Ill., U.S.A.
Archives of Pathology	Arch. Pathol.	1955, **60,** No. 1	Chicago, Ill., U.S.A.
Archives of Pediatrics	Arch. Pediat.	1955, **72,** No. 5	New York, U.S.A.
Archiv der Pharmazie	Arch. Pharm.	1955, **288,** July	Weinheim, Germany
Archiv for Pharmaci og Chemi	Arch. Pharm. Chem.	1955, **62,** Sept.	Copenhagen, Denmark
Archives Portugaises des Sciences Biologiques	Arch. portugaises Sci. biol.	1952–53, **11,** No. 1	Lisbon, Portugal
Archiv für Protistenkunde	Arch. Protistenkunde	1955, **100,** No. 5	Jena, Germany

Title of Journal	*Contracted Title*	*Last Number Scrutinised*	*Place of Publication*
Archiv für Psychiatrie und Nervenkrankheiten	Arch. Psychiat. Nervenkrankh.	1955, **193**, No. 3	Berlin : Heidelberg : Göttingen, Germany
Archivio di Scienze Biologiche	Arch. Sci. biol., Bologna	1955, **39**, No. 4	Bologna, Italy
Archives des Sciences Physiologiques	Arch. Sci. physiol.	1955, **9**, No. 1	Paris, France
Archiv für Tierernährung	Arch. Tierernährung	1955, **5**, No. 1	Berlin, Germany
Archivos Uruguayos de Medicina, Cirugia y Especialidades	Arch. urug. Med.	1954, **44**, No. 5/6	Montevideo, Uruguay
Archivos Venezolanos de Nutricion	Arch. venezol. Nutricion	1954, **5**, No. 2	Caracas, Venezuela
Arkhiv Patologii	Arkh. Patol.	1955, No. 2	Moscow, U.S.S.R.
Arquivos Brasileiros de Nutrição	Arq. brasil. Nutrição	1953, **9**, No. 4	Rio de Janeiro, Brazil
Australian Journal of Agricultural Research	Austral. J. Agric. Res.	1955, **6**, No. 4	Melbourne, Australia
Australian Journal of Biological Sciences	Austral. J. Biol. Sci.	1955, **8**, No. 2	Melbourne, Australia
Australian Journal of Botany	Austral. J. Botany	1955, **3**, No. 1	Melbourne, Australia
Australian Journal of Experimental Biology and Medical Science	Austral. J. Exp. Biol. Med. Sci.	1955, **33**, No. 3	Adelaide, Australia
Australian Journal of Marine and Freshwater Res.	Austral. J. Marine Freshwater Res.	1954, **5**, No. 3	Melbourne, Australia
Australian Journal of Zoology	Austral. J. Zool.	1955, **3**, No. 2	Melbourne, Australia
Australian Veterinary Journal	Austral. Vet. J.	1955, **31**, No. 7	Sydney, Australia
Bacteriological Reviews	Bacteriol. Rev.	1955, **19**, No. 2	Baltimore, Md., U.S.A.
Beiträge zur Pathologischen Anatomie und zur Allgemeinen Pathologie	Beitr. pathol. Anat.	1955, **115**, No. 2	Jena, Germany
Berliner und Münchener Tierärztliche Wochenschrift	Berl. Münch. tierärztl. Wochenschr.	1955, **68**, No. 18	Berlin, Germany
Bi-monthly Bulletin North Dakota Agricultural Experiment Station	Bi-m. Bull. N. Dakota Agric. Exp. Stat.	1954, **17**, No. 2	Fargo, N. Dak., U.S.A.
Biochemical Journal	Biochem. J.	1955, **61**, No. 1	London, England
Biochem. Zeitschrift	Biochem. Ztschr.	1955, **327**, No. 1	Berlin : Göttingen : Heidelberg, Germany
Biochimica et Biophysica Acta	Biochim. biophys. Acta	1955, **18**, No. 1	New York, U.S.A.
Biokhimiya	Biokhimiya	1955, **20**, No. 1	Moscow, U.S.S.R.
Biological Bulletin	Biol. Bull.	1955, **109**, No. 1	Lancaster, Pa., U.S.A.
Biologie Médicale	Biol. méd.	1955, **44**, No. 4	Paris, France
Biological Progress	Biol. Progr.	1952, **2**	New York, U.S.A.
Biological Reviews and Biological Proceedings of the Cambridge Philosophical Society	Biol. Rev.	1955, **30**, No. 3	Cambridge, England
Biometrics	Biometrics	1955, **11**, No. 2	Washington, U.S.A.
Biometrika	Biometrika	1955, **42**, No. 1/2	London, England
Blood, The Journal of Hematology	Blood, J. Hematol.	1955, **10**, No. 8	New York, U.S.A.
Die Bodenkultur	Bodenkultur	1954, **8**, No. 2	Munich, Germany
Boletim de Industria Animal	Bol. Indust. animal, São Paulo	1954, **14**, No. 1	São Paulo, Brazil
Boletin de Instituto Nacional de Investigaciones Agronomicas	Bol. Inst. Nac. Invest. agron., Madrid	1955, **15**, No. 32	Madrid, Spain
Bollettino dell'Istituto Sieroterapico Milanese	Bol. Ist. sieroterap. milan.	1955, **34**, No. 7/8	Milan, Italy
Boletin de la Oficina Sanitaria Panamericana	Bol. Ofic. sanit. panamer.	1955, **38**, No. 3	Washington, D.C., U.S.A.
Bollettino della Società Italiana di Biologia Sperimentale	Bol. Soc. ital. Biol. sper.	1954, **30**, No. 12	Naples, Italy
Brain. A Journal of Neurology	Brain	1955, **78**, No. 2	London, England
British Dental Journal	Brit. Dent. J.	1955, **99**, No. 6	London, England
British Heart Journal	Brit. Heart J.	1955, **17**, No. 3	London, England
British Journal of Animal Behaviour	Brit. J. Animal Behaviour	1955, **3**, No. 3	London, England
British Journal of Dermatology	Brit. J. Dermatol.	1955, **67**, No. 8/9	London, England
British Journal of Experimental Pathology	Brit. J. Exp. Pathol.	1955, **35**, No. 4	London, England
British Journal of Industrial Medicine	Brit. J. Indust. Med.	1955, **12**, No. 3	London, England
British Journal of Nutrition	Brit. J. Nutrition	1955, **9**, No. 3	London, England
British Journal of Ophthalmology	Brit. J. Ophthalmol.	1955, **39**, No. 9	London, England
British Journal of Pharmacology and Chemotherapy	Brit. J. Pharmacol. Chemotherap.	1955, **10**, No. 3	London, England
British Journal of Preventive and Social Medicine	Brit. J. Prev. Social Med.	1955, **9**, No. 2	London, England
British Journal of Radiology	Brit. J. Radiol.	1955, **28**, No. 333	London, England
British Journal of Surgery	Brit. J. Surg.	1955, **43**, No. 177	Bristol, England
British Journal of Urology	Brit. J. Urol.	1955, **27**, No. 2	Bristol, England
British Medical Bulletin	Brit. Med. Bull.	1955, **11**, No. 3	London, England
British Medical Journal	Brit. Med. J.	1955, No. 4941	London, England
British Veterinary Journal	Brit. Vet. J.	1955, **111**, No. 9	London, England
Bulletin de l'Académie Vétérinaire de France	Bull. Acad. vét. France	1955, **28**, No. 4	Paris, France
Bulletin of the Central Food Technological Research Institute	Bull. Central Food Technol. Res. Inst., Mysore	1954, **4**, No. 2	Mysore, India
Bulletin of the History of Medicine	Bull. Hist. Med.	1955, **29**, No. 4	Baltimore, Md., U.S.A.
Bulletin de l'Institut Agronomique et de Recherches de Gembloux	Bull. Inst. agronom. Gembloux	1955, **23**, No. 2	Gembloux, Belgium
Bulletin of the Institute for Medical Research, University of Madrid	Bull. Inst. Med. Res., Univ. Madrid	1954, **7**, No. 2	Madrid, Spain
Bulletin de l'Institut National d'Hygiène	Bull. Inst. nat. Hyg., Paris	1955, **10**, No. 2	Paris, France

Title of Journal	*Contracted Title*	*Last Number Scrutinised*	*Place of Publication*
Bulletin Oxford University Institute of Statistics	Bull. Inst. Statistics Oxford	1955, **17**, No. 2	Oxford, England
Bulletin of the Johns Hopkins Hospital	Bull. Johns Hopkins Hosp.	1955, **97**, No. 1	Baltimore, Md., U.S.A.
Bulletin de Microscopie Appliquée	Bull. Microscop. appl.	1955, **5**, No. 1	Paris, France
Bulletin of the National Institute of Agricultural Sciences, Yahagi, Japan	Bull. Nat. Inst. Agric. Sci., Japan	1954, No. 8	Chiba, Japan
Bulletin de la Société de Chimie Biologique	Bull. Soc. Chim. biol.	1955, **37**, No. 5/6	Paris, France
Bulletin de la Société Chimique de France	Bull. Soc. chim. France	1955, No. 9	Paris, France
Bulletin de la Société de Pathologie Exotique	Bull. Soc. Pathol. exot.	1955, **48**, No. 1	Paris, France
Bulletin de la Société Scientifique d'Hygiène Alimentaire	Bull. Soc. sci. Hyg. aliment.	1955, **43**, No. 6	Paris, France
Bulletin of the Tokyo Medical and Dental University	Bull. Tokyo Med. Dent. Univ.	1955, **2**, No. 1	Tokyo, Japan
Bulletin of the World Health Organization	Bull. World Health Organiz.	1955, **13**, No. 1	Geneva, Switzerland
Calcutta Medical Journal	Calcutta Med. J.	1955, **52**, No. 6	Calcutta, India
Canadian Journal of Agricultural Science	Canad. J. Agric. Sci.	1955, **35**, No. 4	Ottawa, Canada
Canadian Journal of Biochemistry and Physiology	Canad. J. Biochem. Physiol.	1955, **33**, No. 4	Ottawa, Canada
Canadian Journal of Botany	Canad. J. Botany	1955, **33**, No. 4	Ottawa, Canada
Canadian Journal of Chemistry	Canad. J. Chem.	1955, **33**, No. 9	Ottawa, Canada
Canadian Journal of Comparative Medicine	Canad. J. Comp. Med.	1955, **19**, No. 8	Quebec, Canada
Canadian Journal of Microbiology	Canad. J. Microbiol.	1955, **1**, No. 7	Ottawa, Canada
Canadian Journal of Physics	Canad. J. Phys.	1955, **33**, No. 8	Ottawa, Canada
Canadian Journal of Technology	Canad. J. Technol.	1955, **33**, No. 5	Ottawa, Canada
Canadian Journal of Zoology	Canad. J. Zool.	1955, **33**, No. 4	Ottawa, Canada
Cancer Research	Cancer Res.	1955, **15**, No. 7	Chicago, Ill., U.S.A.
Časopis Lékařů Českých	Čas. Lék. čes.	1955, **94**, No. 32	Prague, Czechoslovakia
Cereal Chemistry	Cereal Chem.	1955, **32**, No. 4	Minneapolis, Minn., U.S.A.
Ceylon Journal of Medical Science	Ceylon J. Med. Sci.	1951–53, **8**, No. 3	Colombo, Ceylon
Ceylon Medical Journal	Ceylon Med. J.	1954, **2**, No. 4	—
Chemistry and Industry	Chem. and Indust.	1955, Sept. 17	London, England
Chemische Berichte	Chem. Ber.	1955, **88**, No. 9	Weinheim, Germany
Chemické Listy	Chem. listy	1954, **48**, No. 11	Prague, Czechoslovakia
Chemical Reviews	Chem. Rev.	1955, **55**, No. 4	Baltimore, Md., U.S.A.
Chemist-Analyst	Chemist-Analyst	1955, **44**, No. 1/2	Phillipsburg, N.J., U.S.A.
Child Development	Child Development	1955, **26**, No. 2	Champaign, Ill., U.S.A.
Chinese Medical Journal	Chinese Med. J.	1955, **73**, No. 3	Peking, China
Chronicle of the World Health Organization	Chron. World Health Organiz.	1955, **9**, No. 9	New York, U.S.A.
Circulation	Circulation	1955, **12**, No. 2	Baltimore, Md. U.S.A.
Circulation Research	Circulation Res.	1955, **3**, No. 4	Baltimore, Md. U.S.A.
Clinical Chemistry	Clin. Chem.	1955, **1**, No. 4	Baltimore, Md., U.S.A.
Clinical Science	Clin. Sci.	1955, **14**, No. 3	London, England
Colonial Plant and Animal Products	Colonial Plant Animal Prod.	1955, **5**, No. 1	London, England
Cornell Veterinarian	Cornell Vet.	1955, **45**, No. 3	Ithaca, N.Y., U.S.A.
Comptes Rendus Hebdomadaires de Séances de l'Académie des Sciences	C.R. Acad. Sci.	1955, **241**, No. 10	Paris, France
Comptes Rendus des Travaux du Laboratoire Carlsberg (Série Chimique)	C.R. Lab. Carlsberg (Sér. chim.)	1955, **29**, No. 21	Copenhagen, Denmark
Comptes Rendus des Travaux du Laboratoire Carlsberg (Série Physiologique)	C.R. Lab. Carlsberg (Sér. physiol.)	1955, **25**, No. 12	Copenhagen, Denmark
Comptes Rendus des Séances de la Société de Biologie	C.R. Soc. Biol.	1955, **149**, No. 7/8	Paris, France
Československá Fysiologie	Čsl. fisiol.	1954, **3**, No. 3	Prague, Czechoslovakia
Danish Medical Bulletin	Danish Med. Bull.	1955, **2**, No. 5	Copenhagen, Denmark
Dansk Tidsskrift för Farmaci	Dansk Tidsskr. Farm.	1955, **29**, Sept.	Copenhagen, Denmark
Dental Journal of Australia	Dent. J. Austral.	1955, **27**, No. 3	Sydney, Australia

NUTRITION ABSTRACTS AND REVIEWS

SYMPOSIA

PROCEEDINGS AND CONGRESS REPORTS

It has been the policy of the Editorial Board from the beginning to give full bibliographical references to relevant papers read at meetings of Societies and Congresses but not to give abstracts. So great has the volume of such proceedings become that it has been impossible in recent years to cover all such meetings and the space required to deal with the more important has been excessive. It was therefore proposed, and approved by the Commonwealth Agricultural Bureaux Review Conference, 1955, that we should devote a new section to such reports, giving authors' names and the subject, but not the full title, of papers on nutrition. In this way subscribers can be given an even more complete cover of Society meetings and Congresses in less space, so that there will be more to devote to the growing volume of important full papers on research.

12 AUG
THE LIBRARY
Agricultural Institute
Allahabad.

Books *on Animal Nutrition and Allied Sciences* of all publishers supplied from stock.

FOREIGN BOOKS NOT IN STOCK OBTAINED TO ORDER.

Scientific Lending Library

ANNUAL SUBSCRIPTION, TOWN OR COUNTRY, FROM TWENTY-FIVE SHILLINGS

Bi-monthly list of New Books and New Editions added to the Library, sent post free to any address on request.

The Library Catalogue revised to December, 1949. To subscribers, 17s. 6d. net. To non-subscribers, 35s. net; postage 1s. 8d. Supplement 1950 to 1952. To subscribers 3s. net. To non-subscribers 6s. net; postage 9d.

Second-Hand Books

A constantly changing large stock of second-hand recent editions available. Large and small collections bought.

H. K. LEWIS & Co. Ltd.

LONDON: 136 Gower Street, W.C.1

Telephone: EUSton 4282 (7 lines)

Commonwealth Bureau of Animal Nutrition

Rowett Research Institute, Bucksburn, Aberdeenshire, Scotland

TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch, 1939.

No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch and W. Godden. 5s. 1953.

No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG PART I.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell. 6s. 1948.

No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART I: BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE. M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s. 1951.

No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS. S. D. Morrison. 10s. 6d. 1952.

Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX, CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given

(Those marked with an asterisk are out of print.)

DIET AND DENTAL DISEASE. S. J. Cowell, 1936, **5**, 567.

*A REVIEW OF RECENT WORK ON DIETARY REQUIREMENTS IN PREGNANCY AND LACTATION, WITH AN ATTEMPT TO ASSESS HUMAN REQUIREMENTS. R. C. Garry and D. Stiven, 1936, **5**, 855.

AN ANALYSIS AND COMPARISON OF DIFFERENT METHODS OF CALCULATING THE ENERGY VALUE OF DIETS. N. B. Morey, 1936, **6**, 1.

THE PROTEIN REQUIREMENTS OF LACTATION. S. Morris, 1936, **6**, 273.

THE DETERMINATION OF THE CALCIUM REQUIREMENTS OF MAN. I. Leitch, 1937, **6**, 553; 1938, **8**, 1.

THE RELATIVE POTENCY OF VITAMIN D FROM DIFFERENT SOURCES. E. M. Hume, 1937, **6**, 891.

NUTRITIONAL SCIENCE AND ITS SOCIAL ASPECTS. Sir Richard Gregory, Bart., 1937, **7**, 1.

THE DETERMINATION OF THE PROTEIN REQUIREMENTS OF MAN. I. Leitch and J. Duckworth, 1937, **7**, 257.

THE DETERMINATION OF THE CALORIE REQUIREMENTS OF MAN. J. B. Orr and I. Leitch, 1938, **7**, 509.

RECENT RESEARCH ON VITAMIN E. A. L. Bacharach, 1938, **7**, 811.

*TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1938, **7**, 823.

*THE VITAMIN CONTENT OF HUMAN FOODS AS AFFECTED BY PROCESSES OF COOKING AND CANNING (with tables). M. A. B. Fixsen, 1938, **8**, 281.

THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. A. M. Copping, 1939, **8**, 555.

MAGNESIUM IN ANIMAL NUTRITION. J. Duckworth, 1939, **8**, 841.

PASTEURISATION OF MILK: SOME RECENT ASPECTS. H. D. Kay, 1939, **9**, 1.

CHRONIC FLUORINE INTOXICATION IN DOMESTIC ANIMALS. A. W. Peirce, 1939, **9**, 253.

*THE SIGNIFICANCE OF THE "TRACE ELEMENTS" IN NUTRITION. E. J. Underwood, 1940, **9**, 515.

TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1940, **9**, 795. Price 2s. 6d.

QUALITY AND QUANTITY OF PROTEIN IN RELATION TO HUMAN HEALTH AND DISEASE. D. P. Cuthbertson, 1940, **10**, 1.

VITAMIN A DEFICIENCY AND REQUIREMENTS OF FARM MAMMALS. G. H. Hart, 1940, **10**, 261.

THE DISTRIBUTION OF NICOTINIC ACID IN HUMAN AND ANIMAL FOODS. A. L. Bacharach, 1941, **10**, 459.

THE EFFECT OF DIET ON THE CHEMICAL COMPOSITION, NUTRITIVE VALUE AND HATCHABILITY OF THE EGG. E. M. Cruickshank, 1941, **10**, 645.

NUTRITION AND HUMAN WELFARE. J. B. Orr, 1941, **11**, 3.

INDIAN DIETS AND THEIR IMPROVEMENT. W. R. Aykroyd, 1941, **11**, 171.

COMPONENTS OF THE VITAMIN B_2 COMPLEX. S. Lepkovsky, 1942, **11**, 363.

THE EVOLUTION OF DIETARY STANDARDS. I. Leitch, 1942, **11**, 509.

CHOLESTEROL METABOLISM. R. P. Cook, 1942, **12**, 1.

THE MAGNESIUM REQUIREMENTS OF MAN IN RELATION TO CALCIUM REQUIREMENTS, WITH OBSERVATIONS ON THE ADEQUACY OF DIETS IN COMMON USE. J. Duckworth and G. M. Warnock, 1942, **12**, 167.

THE RÔLE OF VITAMIN CONCENTRATES IN WAR AND IN POST-WAR FOOD RELIEF IN EUROPE. V. P. Sydenstricker, 1943, **12**, 339.

SOME PECULIARITIES OF RUMINANT NUTRITION. H. Goss, 1943, **12**, 531.

THE PRESERVATION OF FOOD. Sir J. Barcroft, 1943, **13**, 1.

*SOME CAUSES OF VARIATION IN THE VITAMIN CONTENT OF PLANTS GROWN FOR FOOD. L. A. Maynard and K. C. Beeson, 1943, **13**, 155.

THE NUTRITIONAL REQUIREMENTS OF THE DOG. L. Michaud and C. A. Elvehjem, 1944, **13**, 323.

PROTEIN HYDROLYSATES IN INTRAVENOUS ALIMENTATION. W. E. Gaunt, 1944, **13**, 501.

NUCLEIC ACIDS AND TISSUE GROWTH. J. N. Davidson and C. Waymouth, 1944, **14**, 1.

*THE WATER ECONOMY OF FARM ANIMALS. I. Leitch and J. S. Thomson, 1944, **14**, 197.

SOME ASPECTS OF RIBOFLAVIN NUTRITION IN MAN. A. M. Copping 1945, **14**, 433.

*THE REQUIREMENT FOR CALCIUM DURING GROWTH. J. O. Holmes, 1945, **14**, 597.

*THE STORAGE OF PROTEIN IN THE ADULT ANIMAL. H. W. Kosterlitz and R. M. Campbell, 1945, **15**, 1.

*DIETARY DEFICIENCIES AND ENERGY METABOLISM. M. Kleiber, 1945, **15**, 207.

THE AMOUNTS OF VITAMIN B_1 IN CEREALS AND THE EXTENT TO WHICH THEY SUPPLY HUMAN REQUIREMENTS IN VARIOUS DIETARIES. W. I. M. Holman, 1946, **15**, 387. Price 2s. 6d.

DIETARY REQUIREMENTS IN HUMAN PREGNANCY AND LACTATION. A REVIEW OF RECENT WORK. R. C. Garry and H. O. Wood, 1946, **15**, 591. Price 3s. 6d.

THE VITAMIN REQUIREMENTS OF SWINE. N. R. Ellis, 1946, **16**, 1.

*THE CORRELATION OF THE AMINO-ACID COMPOSITION OF PROTEINS WITH THEIR NUTRITIVE VALUE. R. J. Block and H. H. Mitchell, 1946, **16**, 249. Price 3s. 6d.

MICROBIOLOGICAL METHODS FOR THE ESTIMATION OF AMINO-ACIDS. B. S. Schweigert and E. S. Snell, 1947, **16**, 497. Price 2s. 6d.

*PRODUCTION AND MODIFICATION OF LIVER DISEASE BY DIET. L. E. Glynn, 1947, **16**, 751.

*THE ROLE OF THE MICROFLORA OF THE ALIMENTARY TRACT OF HERBIVORA WITH SPECIAL REFERENCE TO RUMINANTS. F. Baker, S. T. Harriss, A. T. Phillipson, M. L. McNaught, J. A. B. Smith, S. K. Kon and J. W. G. Porter 1947, **17**, 1. Price 4s.

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews (*continued*)

THE VALUE OF CAPILLARY STRENGTH TESTS IN THE DIAGNOSIS OF VITAMIN C AND VITAMIN P DEFICIENCY IN MAN. H. N. Munro, S. Lazarus and G. H. Bell, 1947, **17**, 291. Price 2s.

THE INFLUENCE OF DIET ON PARODONTAL DISEASE. J. D. King, 1948, **17**, 569. Price 2s. 6d.

METHODS OF ESTIMATING PLASMA AND TOTAL RED CELL VOLUME. E. B. Reeve, 1948, **17**, 811. Price 2s.

*THE NUTRITIVE VALUE OF SILAGE AND DRIED GRASS. S. J. Watson, 1948, **18**, 1. Price 1s. 6d.

*THE EFFECT OF MILLING UPON THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. M. C. Dawbarn, 1949, **18**, 691. Price 2s.

THE CALORIE REQUIREMENT OF ADULT MAN. Ancel Keys, 1949, **19**, 1.

THE MINERAL REQUIREMENTS AND METABOLISM OF POULTRY. Cyril Tyler, 1948, **18**, 261, 473; 1949, **19**, 263. Price 6s.

TECHNIQUE AND INTERPRETATION OF DIETARY SURVEYS. I. Leitch and F. C. Aitken, 1950, **19**, 507.

*THE VITAMIN REQUIREMENTS OF POULTRY. A. S. Hogan, 1950, **19**, 751. Price 6s.

ENERGY FEEDING STANDARDS FOR DAIRY CATTLE. K. L. Blaxter, 1950, **20**, 1. Price 3s.

EVALUATION OF LEANNESS-FATNESS IN MAN: A SURVEY OF METHODS. J. Brožek and Ancel Keys, 1950, **20**, 247. Price 2s.

THE CAUSATION OF PELLAGRA. Harriette Chick, 1951, **20**, 523. Price 2s.

*VITAMIN B_{12}. PART I. E. Lester Smith, 1951, **20**, 795. Price 2s.

VITAMIN B_{12}. PART II. A REVIEW OF THE CLINICAL ASPECTS. C. C. Ungley, 1951, **21**, 1. Price 4s.

EXPANSION OF LIVESTOCK PRODUCTION IN RELATION TO HUMAN NEEDS. Ralph W. Phillips, 1951, **21**, 241. Price 2s.

THE METABOLISM OF FAT IN THE MAMMARY GLAND AND FOETAL TISSUES, WITH REFERENCE TO THE APPLICATION OF ISOTOPIC TRACERS. G. Popják, 1952, **21**, 535. Price 2s. 6d.

THE FLUORINE PROBLEM IN LIVESTOCK FEEDING. H. H. Mitchell and Marjorie Edman, 1952, **21**, 787. Price 2s.

VITAMIN E IN THE NUTRITION OF FARM ANIMALS. K. L. Blaxter and F. Brown, 1952, **22**, 1. Price 2s. 6d.

MEAL HABITS AND THEIR EFFECTS ON PERFORMANCE. R. C. Hutchinson, 1952, **22**, 283. Price 2s.

THE STORAGE OF ELEMENTS IN THE SKELETON. J. Duckworth and R. Hill, 1953, **23**, 1. Price 2s.

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are :—

Canadian Journal of Biochemistry and Physiology	Bi-monthly	$3.00
Canadian Journal of Botany	Bi-monthly	$4.00
Canadian Journal of Chemistry	Monthly	$5.00
Canadian Journal of Microbiology . . .	Bi-monthly	$3.00
Canadian Journal of Physics	Monthly	$4.00
Canadian Journal of Technology	Bi-monthly	$3.00
Canadian Journal of Zoology	Bi-monthly	$3.00

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa 2, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 10, No. 2, 1956. 35s. net

K. L. Blaxter, N. Mc. Graham and F. W. Wainman. Some observations on the digestibility of food by sheep, and related problems.

B. J. Constable, L. J. Harris and R. E. Hughes. Effect of continued administration of cortisone and ACTH on vitamin C levels in guinea-pig adrenals.

Marianne Andersson, A. R. P. Walker and H. C. Falcke. An investigation of the rarety of infantile scurvy among the South African Bantu.

G. A. Dhopeshwarkar, J. C. Trivedi, B. S. Kulkarni, R. S. Satoskar and R. A. Lewis. The effect of vegetarianism and antibiotics upon proteins and vitamin B_{12} in the blood.

J. H. Farrell. The effect on digestibility of methods commonly used to increase the tenderness of lean meat.

Elizabeth J. Castle. The rate of passage of foodstuffs through the alimentary tract of the goat. 2. Studies on growing kids.

W. A. McGillivray, S. Y. Thompson and N. A. Worker. Further studies on the metabolism by rats of intravenously administered aqueous dispersions of carotenoid pigments.

A. E. Bender. Relation between protein efficiency and net protein utilisation.

W. R. Fernell and G. D. Rosen. Microbiological evaluation of protein quality with *Tetrahymena pyriformis* W. 1. Characteristics of growth of the organism and determination of relative nutritive values of intact proteins.

G. D. Rosen and W. R. Fernell. Microbiological evaluation of protein quality with *Tetrahymena pyriformis* W. 2. Relative nutritive values of proteins in foodstuffs.

N. A. Worker. The effect of complete hepatectomy on the utilization by rats and rabbits of intravenously administered aqueous dispersions of carotene.

Published for The Nutrition Society by the **Cambridge University Press, Bentley House, 200 Euston Road, N.W.1.** The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of The Nutrition Society* (2 parts a year) is £7. Single issues of either publication are 35s. each, plus postage.

Zentralblatt für Veterinärmedizin

Edited by

Prof. Dr. M. LERCHE
Free University, Berlin

and

Prof. Dr. H. SPÖRRI
University, Zürich

with the collaboration of many scientists of international repute

The *Zentralblatt für Veterinärmedizin* is an international journal which publishes the results of research in all branches of veterinary medicine. The journal provides the several disciplines of veterinary medicine with information on current aims and results in all the fields of research; it offers the information also to allied sciences so that a fruitful interchange of knowledge and ideas may develop.

Original papers appear in German, English, French or Spanish with summaries in all four languages.

In scope and volume the *Zentralblatt* exceeds other journals of veterinary medicine and in the presentation and value of the papers published is comparable with the best journals serving other sciences.

There are annually 6 parts each of 6 or 7 sheets. The parts of one calendar year form a volume.
Price per sheet (16 pages) about DM. 3. Each part is priced separately.

Zeitschrift für Tierzüchtung und Züchtungsbiologie

Founded in 1924 by C. KRONACHER

Edited by Prof. Dr. J. SCHMIDT
with the collaboration of many international authorities

This journal is the recognised international organ for research on all branches of animal breeding, the biology of animal production and related subjects: racial biology, evolution, genetics, development, growth, constitution and adaptation; osteology and the mechanics of the skeleton, animal nutrition and animal hygiene.

It provides for all technical experts, veterinary officers and biologists a valuable survey of current research.

There are annually about 6 parts and 4 parts are a volume. A part is of about 6 sheets.
Price per sheet of 16 pages about DM. 4. Each part is separately priced.

Published by PAUL PAREY, Lindenstr. 44/47, Berlin, S.W.68 (Westberlin)

VETERINARY REVIEWS AND ANNOTATIONS

(First published April, 1955)

This NEW journal, prepared by the Commonwealth Bureau of Animal Health, Weybridge, consists of reviews of topical subjects written by prominent workers. The reviews give up-to-date and critical summaries of the state of knowledge on their respective subjects and are designed to be of value not only to research workers but to workers in the field and in practice.

Contributions to Part I of Vol. 2, published in April, 1956, are

L. K. WHITTEN. The treatment of tapeworm infestations in man and animals.

CECIL A. HOARE. Toxoplasmosis in animals.

K. L. BLAXTER and ROSEMARY F. MCGILL. Magnesium metabolism in cattle.

I. G. MCINTOSH. Lead poisoning in animals.

ANNUAL SUBSCRIPTION **25s.**

* *Nomenclature of Amino-Acids*

In *Review Articles* it will be that agreed upon by the Editors of the *Journal of the Chemical Society* and o the *Biochemical Journal* published in *Biochem. J.*, 1948, **42**, 1.

In *Abstracts* the nomenclature will be that used in the paper being abstracted.

This is to ***announce*** a new section

in

NUTRITION ABSTRACTS AND REVIEWS

SYMPOSIA

PROCEEDINGS AND CONGRESS REPORTS

It has been the policy of the Editorial Board from the beginning to give full bibliographical references to relevant papers read at meetings of Societies and Congresses but not to give abstracts. So great has the volume of such proceedings become that it has been impossible in recent years to cover all such meetings and the space required to deal with the more important has been excessive. It was therefore proposed, and approved by the Commonwealth Agricultural Bureaux Review Conference, 1955, that we should devote a new section to such reports, giving authors' names and the subject, but not the full title, of papers on nutrition. In this way subscribers can be given an even more complete cover of Society meetings and Congresses in less space, so that there will be more to devote to the growing volume of important full papers on research.

Books *on Animal Nutrition and Allied Sciences* of all publishers supplied from stock.

FOREIGN BOOKS NOT IN STOCK OBTAINED TO ORDER.

Scientific Lending Library

ANNUAL SUBSCRIPTION, TOWN OR COUNTRY, FROM TWENTY-FIVE SHILLINGS

Bi-monthly list of New Books and New Editions added to the Library, sent post free to any address on request.

The Library Catalogue revised to December, 1949. To subscribers, 17s. 6d. net. To non-subscribers, 35s. net; postage 1s. 8d. Supplement 1950 to 1952. To subscribers 3s. net. To non-subscribers 6s. net; postage 9d.

Second-Hand Books

A constantly changing large stock of second-hand recent editions available. Large and small collections bought.

H. K. LEWIS & Co. Ltd.

LONDON: 136 Gower Street, W.C.1

Telephone: EUSton 4282 (7 lines)

Commonwealth Bureau of Animal Nutrition

Rowett Research Institute, Bucksburn, Aberdeenshire, Scotland

TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch, 1939.

No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch and W. Godden. 5s. 1953.

No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG PART I.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell. 6s. 1948.

No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART I: BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE. M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s. 1951.

No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS. S. D. Morrison. 10s. 6d. 1952.

No. 19. TABLES OF THE AMINO ACIDS IN FOODS AND FEEDINGSTUFFS. D. HARVEY. 15s. SEPTEMBER 1956.

Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given

(Those marked with an asterisk are out of print.)

DIET AND DENTAL DISEASE. S. J. Cowell, 1936, **5**, 567.

*A REVIEW OF RECENT WORK ON DIETARY REQUIREMENTS IN PREGNANCY AND LACTATION, WITH AN ATTEMPT TO ASSESS HUMAN REQUIREMENTS. R. C. Garry and D. Stiven, 1936, **5**, 855.

AN ANALYSIS AND COMPARISON OF DIFFERENT METHODS OF CALCULATING THE ENERGY VALUE OF DIETS. N. B. Morey, 1936, **6**, 1.

THE PROTEIN REQUIREMENTS OF LACTATION. S. Morris, 1936, **6**, 273.

THE DETERMINATION OF THE CALCIUM REQUIREMENTS OF MAN. I. Leitch, 1937, **6**, 553; 1938, **8**, 1.

THE RELATIVE POTENCY OF VITAMIN D FROM DIFFERENT SOURCES. E. M. Hume, 1937, **6**, 891.

NUTRITIONAL SCIENCE AND ITS SOCIAL ASPECTS. Sir Richard Gregory, Bart., 1937, **7**, 1.

THE DETERMINATION OF THE PROTEIN REQUIREMENTS OF MAN. I. Leitch and J. Duckworth, 1937, **7**, 257.

THE DETERMINATION OF THE CALORIE REQUIREMENTS OF MAN. J. B. Orr and I. Leitch, 1938, **7**, 509.

RECENT RESEARCH ON VITAMIN E. A. L. Bacharach, 1938, **7**, 811.

*TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1938, **7**, 823.

*THE VITAMIN CONTENT OF HUMAN FOODS AS AFFECTED BY PROCESSES OF COOKING AND CANNING (with tables). M. A. B. Fixsen, 1938, **8**, 281.

THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. A. M. Copping, 1939, **8**, 555.

MAGNESIUM IN ANIMAL NUTRITION. J. Duckworth, 1939, **8**, 841.

PASTEURISATION OF MILK: SOME RECENT ASPECTS. H. D. Kay, 1939, **9**, 1.

CHRONIC FLUORINE INTOXICATION IN DOMESTIC ANIMALS. A. W. Peirce, 1939, **9**, 253.

*THE SIGNIFICANCE OF THE "TRACE ELEMENTS" IN NUTRITION. E. J. Underwood, 1940, **9**, 515.

TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1940, **9**, 795. Price 2s. 6d.

QUALITY AND QUANTITY OF PROTEIN IN RELATION TO HUMAN HEALTH AND DISEASE. D. P. Cuthbertson, 1940, **10**, 1.

VITAMIN A DEFICIENCY AND REQUIREMENTS OF FARM MAMMALS. G. H. Hart, 1940, **10**, 261.

THE DISTRIBUTION OF NICOTINIC ACID IN HUMAN AND ANIMAL FOODS. A. L. Bacharach, 1941, **10**, 459.

THE EFFECT OF DIET ON THE CHEMICAL COMPOSITION, NUTRITIVE VALUE AND HATCHABILITY OF THE EGG. E. M. Cruickshank, 1941, **10**, 645.

NUTRITION AND HUMAN WELFARE. J. B. Orr, 1941, **11**, 3.

INDIAN DIETS AND THEIR IMPROVEMENT. W. R. Aykroyd, 1941, **11**, 171.

COMPONENTS OF THE VITAMIN B_2 COMPLEX. S. Lepkovsky, 1942, **11**, 363.

THE EVOLUTION OF DIETARY STANDARDS. I. Leitch, 1942, **11**, 509.

CHOLESTEROL METABOLISM. R. P. Cook, 1942, **12**, 1.

THE MAGNESIUM REQUIREMENTS OF MAN IN RELATION TO CALCIUM REQUIREMENTS, WITH OBSERVATIONS ON THE ADEQUACY OF DIETS IN COMMON USE. J. Duckworth and G. M. Warnock, 1942, **12**, 167.

THE RÔLE OF VITAMIN CONCENTRATES IN WAR AND IN POST-WAR FOOD RELIEF IN EUROPE. V. P. Sydenstricker, 1943, **12**, 339.

SOME PECULIARITIES OF RUMINANT NUTRITION. H. Goss, 1943, **12**, 531.

THE PRESERVATION OF FOOD. Sir J. Barcroft, 1943, **13**, 1.

*SOME CAUSES OF VARIATION IN THE VITAMIN CONTENT OF PLANTS GROWN FOR FOOD. L. A. Maynard and K. C. Beeson, 1943, **13**, 155.

THE NUTRITIONAL REQUIREMENTS OF THE DOG. L. Michaud and C. A. Elvehjem, 1944, **13**, 323.

PROTEIN HYDROLYSATES IN INTRAVENOUS ALIMENTATION. W. E. Gaunt, 1944, **13**, 501.

NUCLEIC ACIDS AND TISSUE GROWTH. J. N. Davidson and C. Waymouth, 1944, **14**, 1.

*THE WATER ECONOMY OF FARM ANIMALS. I. Leitch and J. S. Thomson, 1944, **14**, 197.

SOME ASPECTS OF RIBOFLAVIN NUTRITION IN MAN. A. M. Copping 1945, **14**, 433.

*THE REQUIREMENT FOR CALCIUM DURING GROWTH. J. O. Holmes, 1945, **14**, 597.

*THE STORAGE OF PROTEIN IN THE ADULT ANIMAL. H. W. Kosterlitz and R. M. Campbell, 1945, **15**, 1.

*DIETARY DEFICIENCIES AND ENERGY METABOLISM. M. Kleiber, 1945, **15**, 207.

THE AMOUNTS OF VITAMIN B_1 IN CEREALS AND THE EXTENT TO WHICH THEY SUPPLY HUMAN REQUIREMENTS IN VARIOUS DIETARIES. W. I. M. Holman, 1946, **15**, 387. Price 2s. 6d.

DIETARY REQUIREMENTS IN HUMAN PREGNANCY AND LACTATION. A REVIEW OF RECENT WORK. R. C. Garry and H. O. Wood, 1946, **15**, 591. Price 3s. 6d.

THE VITAMIN REQUIREMENTS OF SWINE. N. R. Ellis, 1946, **16**, 1.

*THE CORRELATION OF THE AMINO-ACID COMPOSITION OF PROTEINS WITH THEIR NUTRITIVE VALUE. R. J. Block and H. H. Mitchell, 1946, **16**, 249. Price 3s. 6d.

MICROBIOLOGICAL METHODS FOR THE ESTIMATION OF AMINO-ACIDS. B. S. Schweigert and E. S. Snell, 1947, **16**, 497. Price 2s. 6d.

*PRODUCTION AND MODIFICATION OF LIVER DISEASE BY DIET. L. E. Glynn, 1947, **16**, 751.

*THE ROLE OF THE MICROFLORA OF THE ALIMENTARY TRACT OF HERBIVORA WITH SPECIAL REFERENCE TO RUMINANTS. F. Baker, S. T. Harriss, A. T. Phillipson, M. L. McNaught, J. A. B. Smith, S. K. Kon and J. W. G. Porter, 1947, **17**, 1. Price 4s.

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews (*continued*)

THE VALUE OF CAPILLARY STRENGTH TESTS IN THE DIAGNOSIS OF VITAMIN C AND VITAMIN P DEFICIENCY IN MAN. H. N. Munro, S. Lazarus and G. H. Bell, 1947, **17**, 291. Price 2s.

THE INFLUENCE OF DIET ON PARODONTAL DISEASE. J. D. King, 1948, **17**, 569. Price 2s. 6d.

METHODS OF ESTIMATING PLASMA AND TOTAL RED CELL VOLUME. E. B. Reeve, 1948, **17**, 811. Price 2s.

*THE NUTRITIVE VALUE OF SILAGE AND DRIED GRASS. S. J. Watson, 1948, **18**, 1. Price 1s. 6d.

*THE EFFECT OF MILLING UPON THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. M. C. Dawbarn, 1949 **18**, 691. Price 2s.

THE CALORIE REQUIREMENT OF ADULT MAN. Ancel Keys, 1949, **19**, 1.

THE MINERAL REQUIREMENTS AND METABOLISM OF POULTRY. Cyril Tyler, 1948, **18**, 261, 473; 1949, **19**, 263. Price 6s.

TECHNIQUE AND INTERPRETATION OF DIETARY SURVEYS. I. Leitch and F. C. Aitken, 1950, **19**, 507.

*THE VITAMIN REQUIREMENTS OF POULTRY. A. S. Hogan, 1950, **19**, 751. Price 6s.

ENERGY FEEDING STANDARDS FOR DAIRY CATTLE. K. L. Blaxter, 1950, **20**, 1. Price 3s.

EVALUATION OF LEANNESS-FATNESS IN MAN: A SURVEY OF METHODS. J. Brožek and Ancel Keys, 1950, **20**, 247. Price 2s.

THE CAUSATION OF PELLAGRA. Harriette Chick, 1951, **20**, 523. Price 2s.

*VITAMIN B_{12}. PART I. E. Lester Smith, 1951, **20**, 795. Price 2s.

VITAMIN B_{12}. PART II. A REVIEW OF THE CLINICAL ASPECTS. C. C. Ungley, 1951, **21**, 1. Price 4s.

EXPANSION OF LIVESTOCK PRODUCTION IN RELATION TO HUMAN NEEDS. Ralph W. Phillips, 1951, **21**, 241. Price 2s.

THE METABOLISM OF FAT IN THE MAMMARY GLAND AND FOETAL TISSUES, WITH REFERENCE TO THE APPLICATION OF ISOTOPIC TRACERS. G. Popják, 1952, **21**, 535. Price 2s. 6d.

THE FLUORINE PROBLEM IN LIVESTOCK FEEDING. H. H. Mitchell and Marjorie Edman, 1952, **21**, 787. Price 2s.

VITAMIN E IN THE NUTRITION OF FARM ANIMALS. K. L. Blaxter and F. Brown, 1952, **22**, 1. Price 2s. 6d.

MEAL HABITS AND THEIR EFFECTS ON PERFORMANCE. R. C. Hutchinson, 1952, **22**, 283. Price 2s.

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are :—

Canadian Journal of Biochemistry and Physiology	Bi-monthly	$3.00
Canadian Journal of Botany	Bi-monthly	$4.00
Canadian Journal of Chemistry	Monthly	$5.00
Canadian Journal of Microbiology . . .	Bi-monthly	$3.00
Canadian Journal of Physics	Monthly	$4.00
Canadian Journal of Technology	Bi-monthly	$3.00
Canadian Journal of Zoology	Bi-monthly	$3.00

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa 2, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 10, No. 3, 1956. 35s. net

B. S. PLATT. Obituary Notice (Sir Edward Mellanby).

B. M. NICOL. The nutrition of Nigerian children, with particular reference to their energy requirements.

E. G. HOLMES, E. R. JONES, MARGARET D. LYLE and MARGARET W. STANIER. Malnutrition in in African adults. 3. Effect of diet on body composition.

J. N. AITKEN and J. A. CRICHTON. The effect of hexoestrol implantation on growth and certain carcass characteristics of fattening steers.

J. C. GILL, W. THOMSON and J. A. CRICHTON. The effect of hexoestrol implantation on the fattening of lambs.

R. L. HARTLES, F. E. LAWTON and G. L. SLACK. Experimental dental caries in the albino rat. The production of carious lesions in animals maintained on a finely powdered purified diet containing 67 per cent. sucrose.

V. H. BOOTH. Disappearance of carotene from the alimentary tract of vitamin A—deficient rats.

T. G. TAYLOR and J. H. MOORE. The effects of calcium depletion on the chemical composition of bone minerals in laying hens.

The late EDWARD MELLANBY. Preliminary experiments on the effect of methionine sulphoximine on the developing chick.

Published for The Nutrition Society by the **Cambridge University Press, Bentley House, 200 Euston Road N.W.1.** The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of The Nutrition Society* (2 parts a year) is £7. Single issues of either publication are 35s. each, plus postage.

WIESEN UND WEIDEN

MEADOW AND PASTURE

Treatment, Improvement and Use of Pasture

BY

PROF. DR. E. KLAPP

3rd edition, 1956 526 pages with 175 illustrations

Linen : D.M. 33.60

In this publication the laying-down of pasture, its proper care, manurial treatment and use, are treated in a fully modern way. It is the standard work on modern pasture management.

"In this book German and the rest of European Agriculture has at hand a standard work which will contribute greatly to further advances in crop management. The information presented in it about the life of the grass sod as basis for the management of pasture is a summary of scientific discoveries all over the world and of the extensive practical observations of the author in Europe and overseas."—*The Animal Breeder.*

GRUNDZÜGE DER FÜTTERUNGSLEHRE

FUNDAMENTALS OF FEEDING

FOUNDED BY PROF. DR. O. KELLNER

COMPLETELY REVISED BY PROF. DR. A. SCHEUNERT

11th Edition, 1952 331 pages with 7 tables

Half-cloth D.M. 18.80

For 50 years this book has had a firmly established place in the field of animal nutrition. Clear examples make the physiological statements easily understood. Useful tables show the composition of feedingstuffs and their digestibility for different animals. This edition revised by the well-known veterinary physiologist, Prof. Dr. Scheunert, is still the most reliable guide in all questions of feeding.

To be ordered through any bookseller

Verlag PAUL PAREY, Berlin, S.W. 68, Lindenstrasse 44/47

VETERINARY REVIEWS AND ANNOTATIONS

(First published April, 1955)

This **NEW** journal, prepared by the Commonwealth Bureau of Animal Health, Weybridge, consists of reviews of topical subjects written by prominent workers. The reviews give up-to-date and critical summaries of the state of knowledge on their respective subjects and are designed to be of value not only to research workers but to workers in the field and in practice.

Contributions to Part 2 of Vol. 2, to appear in October, 1956, are

J. R. M. INNES and R. EISENSTEIN. Sarcosporidiosis in man and animals.

A. T. JOHNS. Review on bloat.

J. SEAMER. Review on piglet anæmia.

J. G. BROTHERSTON. Rinderpest: control by modified virus vaccines [Part I.].

ANNUAL SUBSCRIPTION **25s.**

NUTRITION ABSTRACTS AND REVIEWS

SYMPOSIA

PROCEEDINGS AND CONGRESS REPORTS

It has been the policy of the Editorial Board from the beginning to give full bibliographical references to relevant papers read at meetings of Societies and Congresses but not to give abstracts. So great has the volume of such proceedings become that it has been impossible in recent years to cover all such meetings and the space required to deal with the more important has been excessive. It was therefore proposed, and approved by the Commonwealth Agricultural Bureaux Review Conference, 1955, that we should devote a new section to such reports, giving authors' names and the subject, but not the full title, of papers on nutrition. In this way subscribers can be given an even more complete cover of Society meetings and Congresses in less space, so that there will be more to devote to the growing volume of important full papers on research.

TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch, 1939.

No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch and W. Godden. 5s. 1953.

No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG PART I.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell. 6s. 1948.

No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART I: BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE. M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s. 1951.

No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS. S. D. Morrison. 10s. 6d. 1952.

No. 19. TABLES OF THE AMINO ACIDS IN FOODS AND FEEDINGSTUFFS. D. HARVEY. 15s. 1956.

Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX, CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given

(Those marked with an asterisk are out of print.)

DIET AND DENTAL DISEASE. S. J. Cowell, 1936, **5**, 567.

*A REVIEW OF RECENT WORK ON DIETARY REQUIREMENTS IN PREGNANCY AND LACTATION, WITH AN ATTEMPT TO ASSESS HUMAN REQUIREMENTS. R. C. Garry and D. Stiven, 1936, **5**, 855.

AN ANALYSIS AND COMPARISON OF DIFFERENT METHODS OF CALCULATING THE ENERGY VALUE OF DIETS. N. B. Morey, 1936, **6**, 1.

THE PROTEIN REQUIREMENTS OF LACTATION. S. Morris, 1936, **6**, 273.

THE DETERMINATION OF THE CALCIUM REQUIREMENTS OF MAN. I. Leitch, 1937, **6**, 553; 1938, **8**, 1.

THE RELATIVE POTENCY OF VITAMIN D FROM DIFFERENT SOURCES. E. M. Hume, 1937, **6**, 891.

NUTRITIONAL SCIENCE AND ITS SOCIAL ASPECTS. Sir Richard Gregory, Bart., 1937, **7**, 1.

THE DETERMINATION OF THE PROTEIN REQUIREMENTS OF MAN. I. Leitch and J. Duckworth, 1937, **7**, 257.

THE DETERMINATION OF THE CALORIE REQUIREMENTS OF MAN. J. B. Orr and I. Leitch, 1938, **7**, 509.

RECENT RESEARCH ON VITAMIN E. A. L. Bacharach, 1938, **7**, 811.

*TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1938, **7**, 823.

*THE VITAMIN CONTENT OF HUMAN FOODS AS AFFECTED BY PROCESSES OF COOKING AND CANNING (with tables). M. A. B. Fixsen, 1938, **8**, 281.

THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. A. M. Copping, 1939, **8**, 555.

MAGNESIUM IN ANIMAL NUTRITION. J. Duckworth, 1939, **8**, 841.

PASTEURISATION OF MILK: SOME RECENT ASPECTS. H. D. Kay, 1939, **9**, 1.

CHRONIC FLUORINE INTOXICATION IN DOMESTIC ANIMALS. A. W. PEIRCE, 1939, **9**, 253.

*THE SIGNIFICANCE OF THE "TRACE ELEMENTS" IN NUTRITION. E. J. Underwood, 1940, **9**, 515.

TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1940, **9**, 795. Price 2s. 6d.

QUALITY AND QUANTITY OF PROTEIN IN RELATION TO HUMAN HEALTH AND DISEASE. D. P. Cuthbertson, 1940, **10**, 1.

VITAMIN A DEFICIENCY AND REQUIREMENTS OF FARM MAMMALS. G. H. Hart, 1940, **10**, 261.

THE DISTRIBUTION OF NICOTINIC ACID IN HUMAN AND ANIMAL FOODS. A. L. Bacharach, 1941, **10**, 459.

THE EFFECT OF DIET ON THE CHEMICAL COMPOSITION, NUTRITIVE VALUE AND HATCHABILITY OF THE EGG. E. M. Cruickshank, 1941, **10**, 645.

NUTRITION AND HUMAN WELFARE. J. B. Orr, 1941, **11**, 3.

INDIAN DIETS AND THEIR IMPROVEMENT. W. R. Aykroyd, 1941, **11**, 171.

COMPONENTS OF THE VITAMIN B_2 COMPLEX. S. Lepkovsky, 1942, **11**, 363.

THE EVOLUTION OF DIETARY STANDARDS. I. Leitch, 1942, **11**, 509.

CHOLESTEROL METABOLISM. R. P. Cook, 1942, **12**, 1.

THE MAGNESIUM REQUIREMENTS OF MAN IN RELATION TO CALCIUM REQUIREMENTS, WITH OBSERVATIONS ON THE ADEQUACY OF DIETS IN COMMON USE. J. Duckworth and G. M. Warnock, 1942, **12**, 167.

THE RÔLE OF VITAMIN CONCENTRATES IN WAR AND IN POST-WAR FOOD RELIEF IN EUROPE. V. P. Sydenstricker, 1943, **12**, 339.

SOME PECULIARITIES OF RUMINANT NUTRITION. H. Goss, 1943, **12**, 531.

THE PRESERVATION OF FOOD. Sir J. Barcroft, 1943, **13**, 1.

*SOME CAUSES OF VARIATION IN THE VITAMIN CONTENT OF PLANTS GROWN FOR FOOD. L. A. Maynard and K. C. Beeson, 1943, **13**, 155.

THE NUTRITIONAL REQUIREMENTS OF THE DOG. L. Michaud and C. A. Elvehjem, 1944, **13**, 323.

PROTEIN HYDROLYSATES IN INTRAVENOUS ALIMENTATION. W. E. Gaunt, 1944, **13**, 501.

NUCLEIC ACIDS AND TISSUE GROWTH. J. N. Davidson and C. Waymouth, 1944, **14**, 1.

*THE WATER ECONOMY OF FARM ANIMALS. I. Leitch and J. S. Thomson, 1944, **14**, 197.

SOME ASPECTS OF RIBOFLAVIN NUTRITION IN MAN. A. M. Copping 1945, **14**, 433.

*THE REQUIREMENT FOR CALCIUM DURING GROWTH. J. O. Holmes, 1945, **14**, 597.

*THE STORAGE OF PROTEIN IN THE ADULT ANIMAL. H. W. Kosterlitz and R. M. Campbell, 1945, **15**, 1.

*DIETARY DEFICIENCIES AND ENERGY METABOLISM. M. Kleiber, 1945, **15**, 207.

THE AMOUNTS OF VITAMIN B_1 IN CEREALS AND THE EXTENT TO WHICH THEY SUPPLY HUMAN REQUIREMENTS IN VARIOUS DIETARIES. W. I. M. Holman, 1946, **15**, 387. Price 2s. 6d.

DIETARY REQUIREMENTS IN HUMAN PREGNANCY AND LACTATION. A REVIEW OF RECENT WORK. R. C. Garry and H. O. Wood, 1946, **15**, 591. Price 3s. 6d.

THE VITAMIN REQUIREMENTS OF SWINE. N. R. Ellis, 1946, **16**, 1.

*THE CORRELATION OF THE AMINO-ACID COMPOSITION OF PROTEINS WITH THEIR NUTRITIVE VALUE. R. J. Block and H. H. Mitchell, 1946, **16**, 249. Price 3s. 6d.

MICROBIOLOGICAL METHODS FOR THE ESTIMATION OF AMINO-ACIDS. B. S. Schweigert and E. S. Snell, 1947, **16**, 497. Price 2s. 6d.

*PRODUCTION AND MODIFICATION OF LIVER DISEASE BY DIET. L. E. Glynn, 1947, **16**, 751.

*THE ROLE OF THE MICROFLORA OF THE ALIMENTARY TRACT OF HERBIVORA WITH SPECIAL REFERENCE TO RUMINANTS. F. Baker, S. T. Harriss, A. T. Phillipson, M. L. McNaught, J. A. B. Smith, S. K. Kon and J. W. G. Porter, 1947, **17**, 1. Price 4s.

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews (*continued*)

THE VALUE OF CAPILLARY STRENGTH TESTS IN THE DIAGNOSIS OF VITAMIN C AND VITAMIN P DEFICIENCY IN MAN. H. N. Munro, S. Lazarus and G. H. Bell, 1947, **17**, 291. Price 2s.

THE INFLUENCE OF DIET ON PARODONTAL DISEASE. J. D. King, 1948, **17**, 569. Price 2s. 6d.

METHODS OF ESTIMATING PLASMA AND TOTAL RED CELL VOLUME. E. B. Reeve, 1948, **17**, 811. Price 2s.

*THE NUTRITIVE VALUE OF SILAGE AND DRIED GRASS. S. J. Watson, 1948, **18**, 1. Price 1s. 6d.

*THE EFFECT OF MILLING UPON THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. M. C. Dawbarn, 1949, **18**, 691. Price 2s.

THE CALORIE REQUIREMENT OF ADULT MAN. Ancel Keys, 1949, **19**, 1.

THE MINERAL REQUIREMENTS AND METABOLISM OF POULTRY. Cyril Tyler, 1948, **18**, 261, 473; 1949, **19**, 263. Price 6s.

TECHNIQUE AND INTERPRETATION OF DIETARY SURVEYS. I. Leitch and F. C. Aitken, 1950, **19**, 507.

*THE VITAMIN REQUIREMENTS OF POULTRY. A. S. Hogan, 1950, **19**, 751. Price 6s.

ENERGY FEEDING STANDARDS FOR DAIRY CATTLE. K. L. Blaxter, 1950, **20**, 1. Price 3s.

EVALUATION OF LEANNESS-FATNESS IN MAN: A SURVEY OF METHODS. J. Brožek and Ancel Keys, 1950, **20**, 247. Price 2s.

THE CAUSATION OF PELLAGRA. Harriette Chick, 1951, **20**, 523. Price 2s.

*VITAMIN B_{12}. PART I. E. Lester Smith, 1951, **20**, 795. Price 2s.

VITAMIN B_{12}. PART II. A REVIEW OF THE CLINICAL ASPECTS. C. C. Ungley, 1951, **21**, 1. Price 4s.

EXPANSION OF LIVESTOCK PRODUCTION IN RELATION TO HUMAN NEEDS. Ralph W. Phillips, 1951, **21**, 241. Price 2s.

THE METABOLISM OF FAT IN THE MAMMARY GLAND AND FOETAL TISSUES, WITH REFERENCE TO THE APPLICATION OF ISOTOPIC TRACERS. G. Popják, 1952, **21**, 535. Price 2s. 6d.

THE FLUORINE PROBLEM IN LIVESTOCK FEEDING. H. H. Mitchell and Marjorie Edman, 1952, **21**, 787. Price 2s.

VITAMIN E IN THE NUTRITION OF FARM ANIMALS. K. L. Blaxter and F. Brown, 1952, **22**, 1. Price 2s. 6d.

MEAL HABITS AND THEIR EFFECTS ON PERFORMANCE. R. C. Hutchinson, 1952, **22**, 283. Price 2s.

THE STORAGE OF ELEMENTS IN THE SKELETON. J. Duckworth and R. Hill, 1953, **23**, 1. Price 2s.

FAO. W. R. Aykroyd, 1953, **23**, 229. Price 2s.

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are :—

Canadian Journal of Biochemistry and Physiology	Bi-monthly	$3.00
Canadian Journal of Botany	Bi-monthly	$4.00
Canadian Journal of Chemistry	Monthly	$5.00
Canadian Journal of Microbiology . . .	Bi-monthly	$3.00
Canadian Journal of Physics	Monthly	$4.00
Canadian Journal of Technology	Bi-monthly	$3.00
Canadian Journal of Zoology	Bi-monthly	$3.00

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa 2, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 10, No. 4, 1956. 35s. net

B. M. NICOL. The nutrition of Nigerian children, with particular reference to their ascorbic-acid requirements.

D. C. EDWARDS and R. A. DARROCH. The synthesis of lysine by the lactating goat.

E. AAES-JØRGENSEN, J. P. FUNCH, P. F. ENGEL and H. DAM. The role of fat in the diet of rats. 9. Influence on growth and histology of diets with hydrogenated arachis oil or no fat, supplemented with linoleic acid or raw skim milk, and of crude casein compared with Vitamin Test Casein.

CECILIA D. DICKINSON and PATRICIA P. SCOTT. Nutrition of the cat. 1. A practical stock diet supporting growth and reproduction.

CECILIA D. DICKINSON and PATRICIA P. SCOTT. Nutrition of the cat. 2. Protein requirements for growth of weanling kittens and young cats maintained on a mixed diet.

E. AAES-JØRGENSEN, J. P. FUNCH and H. DAM. The role of fat in the diet of rats. 10. Influence on reproduction of hydrogenated arachis oil as the sole dietary fat.

A. W. BOYNE, ROSA M. CAMPBELL, D. P. CUTHBERTSON and J. DAVIDSON. Changes in composition of the digesta along the alimentary tract of sheep.

N. G. BAPTIST and B. P. M. PERERA. Essential amino-acids of some tropical cereal millets.

ELIZABETH J. CASTLE. The rate of passage of foodstuffs through the alimentary tract of the goat. 3. The intestines.

CYNTHIA D. COMBRIDGE. The effect of pyridoxin deficiency on certain organs of the rat.

D. H. M. WOOLLAM and J. W. MILLEN. The relationship between hypovitaminosis A and the cerebrospinal-fluid pressure in the chick: an experimental study.

ELSIE M. WIDDOWSON and R. A. MCCANCE. The effects of chronic undernutrition and of total starvation on growing and adult rats.

LESLIE J. HARRIS, B. J. CONSTABLE, A. N. HOWARD and AUDREY LEADER. Vitamin C economy of rabbits.

Published for The Nutrition Society by the **Cambridge University Press, Bentley House, 200 Euston Road, N.W.1.** The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of The Nutrition Society* (2 parts a year) is £7. Single issues of either publication are 35s. each, plus postage.

MEADOW AND PASTURE

(WIESEN UND WEIDEN)

Treatment, Improvement and Use of Pasture

BY

PROF. DR. E. KLAPP

3rd edition, 1956 — 526 pages with 175 illustrations

Linen : D.M. 33.60

In this publication the laying-down of pasture, its proper care, manurial treatment and use, are treated in a fully modern way. It is the standard work on modern pasture management.

"In this book German and the rest of European Agriculture has at hand a standard work which will contribute greatly to further advances in crop management. The information presented in it about the life of the grass sod as basis for the management of pasture is a summary of scientific discoveries all over the world and of the extensive practical observations of the author in Europe and overseas." *The Animal Breeder.*

FUNDAMENTALS OF FEEDING

(GRUNDZÜGE DER FÜTTERUNGSLEHRE)

FOUNDED BY PROF. DR. O. KELLNER

COMPLETELY REVISED BY PROF. DR. A. SCHEUNERT

11th Edition, 1952 — 331 pages with 7 tables

Half-cloth D.M. 18.80

For 50 years this book has had a firmly established place in the field of animal nutrition. Clear examples make the physiological statements easily understood. Useful tables show the composition of feedingstuffs and their digestibility for different animals. This edition revised by the well-known veterinary physiologist, Prof. Dr. Scheunert, is still the most reliable guide in all questions of feeding.

To be ordered through any bookseller

Verlag PAUL PAREY, Berlin SW 68, Lindenstrasse 44/47

VETERINARY REVIEWS AND ANNOTATIONS

(First published April, 1955)

This NEW journal, prepared by the Commonwealth Bureau of Animal Health, Weybridge, consists of reviews of topical subjects written by prominent workers. The reviews give up-to-date and critical summaries of the state of knowledge on their respective subjects and are designed to be of value not only to research workers but to workers in the field and in practice.

Contributions to Part 2 of Vol. 2, to appear in October, 1956, are

J. R. M. INNES and R. EISENSTEIN. Sarcosporidiosis in man and animals.

A. T. JOHNS. Review on bloat.

J. SEAMER. Review on piglet anæmia.

J. G. BROTHERSTON. Rinderpest: control by modified virus vaccines [Part I.].

AUTHOR INDEX

* *Nomenclature of Amino-Acids*

In *Review Articles* it will be that agreed upon by the Editors of the *Journal of the Chemical Society* and of the *Biochemical Journal* published in *Biochem. J.*, 1948, **42**, 1.

In *Abstracts* the nomenclature will be that used in the paper being abstracted.

INTRODUCTION

WE may say that the modern science of nutrition originated from or at least was greatly stimulated by the beriberi research. In the 19th century the classical science of nutrition was built up by formidable experimental work and scientific interpretation by several great men and in a great many laboratories, chemical, physiological and veterinary.

Voit, one of the founders of the classical science of nutrition, realised in 1881 that that science was founded on experiments with natural foodstuffs and not with pure proteins, carbohydrates, fats and mineral salts. He wrote on page 19 of *Hermann's Handbuch der Physiologie*: "Jedoch wäre es wohl möglich und ganz verdienstvoll, die Grundversuche . . . mit den reinen Stoffen zu wiederholen, obwohl sich dabei sicherlich im Wesentlichen keine anderen Resultaten ergeben werden" (Voit, 1881). Lunin, a pupil of Bunge in Basle, soon afterwards made the experiments that Voit had predicted as unnecessary, but the result was unexpected. Lunin fed mice on a diet purified as far as possible, consisting of pure casein, pure carbohydrates, fats and mineral salts, in the proportion in which those ingredients occurred in milk powder. Young mice did not grow well on the mixture and all died in a short time. On the other hand, mice on a milk powder diet grew well and remained healthy (Lunin, 1881). Therefore, Lunin came to the conclusion that a natural food such as milk must contain, besides the known, principal ingredients, small quantities of unknown substances essential to life. His statement was so much in contradiction to the classical theory that at first it made little impression on the scientific world. Lunin's chief, Professor Bunge, had been doing important work on the nutritive importance of sodium chloride and other mineral salts and so thought that perhaps a wrong proportion of the mineral salts was responsible for his pupil's odd results. It was only after decades that the famous American nutrition workers Osborne and Mendel (1911; 1913) took protein-free milk powder as a source of mineral

salts in suitable proportion, and realised that it contained unknown ingredients, essential to life.

Historically, it was chiefly researches on the cause of beriberi that put an end to acceptance of the former classical theory of nutrition.

Of great importance for the acceptance by the scientific and medical world of the idea that small amounts of specific accessory constituents of the diet have indispensable functions was the support given to it by the biochemist, Hopkins. Hopkins had found that the addition of a small quantity of milk was essential for the growth and wellbeing of mice given a purified artificial diet (Hopkins, 1912).

Beriberi

Beriberi was known for centuries in several Far-Eastern rice-eating countries. Already in the year 1611 the first Governor-General of the Dutch East India Company wrote that in the Dutch East Indies there was a disease named beriberi which caused paralysis in the hands and feet. Later, Bontius in Batavia, the capital of the former Dutch East Indies, now Djakarta in Indonesia, was the first European physician to write about this disease (Bontius, 1642). In those early days only sporadic cases were seen, but the situation changed for the worse in the nineteenth century after the introduction of machine-milled rice. In all rice-eating peoples several diseases with different names were recognised by the end of the nineteenth century as being identical with beriberi or *kakke*, as it was called in Japan.

Scheube (1882) and Baelz (1882), two physicians working in Japan, were the first to make extensive studies of *kakke* and to perform autopsies. They were especially impressed by the diminished activity of the patients, which they ascribed to a peripheral, multiple, subacute neuritis. Later Pekelharing and Winkler (1887) performed scores of autopsies and found that degeneration of the peripheral nerves was always present. The nucleated sheath of Schwann remained intact, but the axis-cylinder was present only near the nodes of Ranvier, where the medullary substance had often disappeared over a large area.

Pathologists agree that the essential changes in beriberi fall into three groups: changes in the nervous system, changes in the heart function, anasarca and effusion.

In general, three forms of beriberi are distinguished, the dry, the wet, and the cardiac or pernicious, but the forms are often mixed. In the dry form, nerve degeneration leading to paralysis is the most obvious sign. In the wet form, oedema is the sign by which the disease is easily recognised even by laymen. Each of these types can change into the other and when the wet changes into the dry, the patient may lose several pounds in weight by profuse urination; paralysis may then appear. In the early stages dry beriberi is often characterised by an unsteady gait; in mild forms the extensors alone are involved and there is toe drop. Both the wet and the dry type of beriberi may suddenly change to the cardiac or pernicious form, which, if not properly treated, leads to a painful death in a few hours (see p. 10).

Rice and its Processing

The ears of rice after harvesting are threshed so that the grains, usually called "paddy", are shed. Three layers can be distinguished in a husked rice grain. The outer layer or pericarp is very thin and is known as the "silverskin"; in many kinds of rice it is white, but in others it is grey or red or nearly black. The middle layer, the sub-pericarpal or aleurone layer, contains the greater part of the fat and part of the proteins of the grain. The third and innermost layer constitutes the largest part of the rice grain and consists chiefly of starch. At one end of the grain is the embryo or germ.

The paddy grains after being freed from the husks are processed in different ways. Before the introduction of steam-powered rice mills the husked rice was pounded by the farmers themselves with a wooden pestle in a wooden mortar, usually formed from the hollowed-out trunk of a tree. After the hulls had been removed from the grain, the mixture was placed on trays and tossed skilfully into the air. The rice fell back into the tray and the wind carried away the hulls. By this process a great deal of the outer layer was left on the grain. It is possible in this way to remove all the pericarp, sub-pericarp and germ, but it takes so long that it is done only in special cases. In the latter half of the nineteenth century steam-powered mills were introduced in the larger cities of rice-eating countries. The mills removed all the outer layers of the rice grain and the resulting product was the familiar polished, white rice containing no significant amount of the sub-pericarp or germ.

In Malaya and in some regions of India the paddy is processed differently. Fletcher (1909) described it in this way: "The unhusked grain or paddy is soaked in water for twelve to twenty-four hours or even longer. It is then heated in vessels containing water over a slow fire until the husks burst. The third stage in the preparation consists of spreading out the grain and drying it in the sun; when this has been completed, it should be possible to separate the husks from the seed by light rubbing between the palms of the hands. The rice is then husked by pounding, or is taken to the mills, where

the same process is effected by the millstone, but it is not polished by the rapidly revolving stones against the fine wire gauze after the manner of the white rice." The rice processed in this way is called " cured " or " parboiled " rice. In later years, the whole process became industrialised, and its product, called " converted rice ", was used on a large scale in the Southern United States. By the methods now available for estimating the content of vitamin B_1, it has been shown that converted or parboiled rice has nearly the same vitamin B_1 content as crude rice.

A by-product of the rice mills is rice bran, known in Malaya as " *dedek* ", which contains the pericarp, the aleurone layer and the germ. It is sold as feed for fowls and pigs.

Rice is not rich in proteins, containing only from 5 to 8 per cent., but they are of good nutritive value with a high percentage of essential amino-acids. The content of fat is less than 1 per cent., and of mineral salts 1 per cent. or less, so that rice is predominantly a carbohydrate food.

Early Researches on the Cause of Beriberi

Until the end of the nineteenth century two causes of beriberi were suggested, infection and intoxication, and early research was consequently directed towards one or other of them.

The German physicians Baelz (1882) and Scheube (1882), who worked in Japan, formed the opinion that beriberi was a *panneuritis endemica* (Baelz, 1882), caused by an infection. The frequency of the disease in such crowded places as prisons, barracks, plantations and ships pointed to infection. Many other investigators tried to prove that beriberi was an infectious disease and some even designated certain micro-organisms as the specific cause. But, in the long run, nobody has been able to sustain the claim to have isolated a specific causative microbe.

Other scientists attempted to find a specific chemical poison in the rice diet and present in the rice, because beriberi was a disease particularly prevalent among rice-eating communities. Examples of diseases caused by poisonous or poisoned foods were known, such as lathyrism and ergotism. Thus it was thought that rice might contain a toxin or might become poisonous by processing or storing. It was not suspected by anyone that deficiency of an essential food component in the processed rice might be the cause of beriberi because, according to the contemporary theory of nutrition, all the necessary components of a diet were known and were present in rice, though perhaps the protein content was somewhat low.

In 1873 the Dutch naval doctor, van Leent, studied the morbidity and mortality from beriberi in the Indian and European crews of the Dutch navy. He found a far greater mortality among the Indians than among the Europeans, which he ascribed to differences between the diets; that of the Indians consisted chiefly of rice while that of the Europeans was more mixed and contained larger amounts of protein and fat. He therefore changed the diet of the Indians to that of the Europeans, a measure which led to a great reduction in the beriberi morbidity among the Indian crew (van Leent, 1880).

About ten years later, Takaki, chief of the medical service of the Japanese navy, introduced similar changes into the diet of the Japanese navy personnel, the amount of rice being reduced to 175 g. a day. Takaki's reform of the former rice diet produced a great reduction in the incidence of beriberi in the Japanese navy also, and the disease was finally eradicated (Takaki, 1887; 1906).

Schaumann (1908), working in the Tropenhygienisches Institut at Hamburg, made extensive investigations on the cause of beriberi and came to the conclusion that it was a metabolic disease caused by deficiency of organic phosphorus compounds and insufficient absorption of them from the gut.

Modern View of the Cause of Beriberi

Modern investigations on the cause of beriberi originated in the work of the Dutch investigators, Eijkman and Grijns, in Batavia, now called Djakarta.

As has already been shown, beriberi occurred sporadically until the middle of the nineteenth century, but after about 1870, with the introduction of the steam-powered rice mills, the incidence of the disease rose steeply, chiefly in prisons and barracks. In Java, prisons existed where a sentence of longer than three months was equivalent to capital punishment, because after that time nearly all the prisoners developed beriberi and died. The war against the pirates in Atjeh in the north of Sumatra became seriously hampered, because soldiers who had remained longer than three months in the barracks were attacked by beriberi. In those circumstances the Dutch Government in 1886 sent to the Dutch East Indies a commission, consisting of a neurologist, Dr. C. Winkler, and a hygienist and bacteriologist, Prof. C. A. Pekelharing, to investigate the cause of beriberi and to advise on remedies against it. The commission had as assistant a young military surgeon, Dr. Christian Eijkman. After a thorough examination, Pekelharing thought he had discovered the cause of beriberi in a microbe, a coccus, which he found in beriberi patients but not in healthy people (Pekelharing and Winkler, 1887). The obvious remedy was, therefore, disinfection

of the barracks and prisons. The commission then returned to Holland.

Pekelharing was not, however, fully convinced that he had found the specific remedy. He therefore urged the Government to exempt Dr. Eijkman from military service and to give him the opportunity to continue research on beriberi. He was even granted a small laboratory in the military hospital at Batavia, with the grand name of Laboratory for Pathological Anatomy and Bacteriology. Here Eijkman tried to confirm the infection theory of the commission by inoculating fowls as experimental animals with supposedly infectious material such as blood and urine from beriberi patients or with material from corpses of patients who had died from beriberi.

From the work of several investigators and of Eijkman himself, it was known that polyneuritis was one of the signs of beriberi, so Eijkman examined his fowls for polyneuritis. At first he did not find any sign of a disease like beriberi in the fowls. They were being fed at the time on crude rice. After some months, however, when they were being fed on the boiled, polished rice that was left over from the hospital table, he observed signs that reminded him of human beriberi, particularly in regard to polyneuritis. By staining with osmic acid according to the methods of Marchi, he found the same appearances in nerves from the polyneuritic fowls as in nerves from human beings who had died from beriberi. It was, however, not only birds inoculated with the supposed infecting bacilli which showed the signs, but also non-infected, control fowls. Six months later, all the diseased fowls recovered and none showed fresh signs. The question was, what could have caused the appearance and later the disappearance of the polyneuritis? It had appeared about a month after the introduction of white, polished rice into the diet of the fowls. Some months later a new chief of the hospital forbade the use of the hospital luxury rice for the animals. The fowls were then again fed on cheap, crude rice and some weeks later the epizoötic ceased completely.

Was it possible that the change in the kind of rice might have caused the change in the health of the fowls? The possibility was easily tested. Eijkman took two groups of non-inoculated fowls; one group was fed on crude rice, the other on white, polished rice from which the germ and pericarp had been removed. The result was decisive; the birds given polished rice showed the beriberi-like signs, those given crude rice remained healthy (Eijkman, 1890; a short account in German, 1897*a*).

In order to examine whether possibly a toxic substance had been developed in the white, polished rice during storage, crude rice was milled and polished in the laboratory. The white, polished rice thus obtained produced polyneuritis in the fowls, which could be cured by giving the germ and pericarp separated from the crude rice by the milling process. The addition of rice hulls or other indigestible material like chalk or small pebbles to the polished rice did not prevent or cure the polyneuritis. It was found that the protein content of the germ and pericarp of the rice was somewhat higher than that of polished rice, and it was possible that the polyneuritic signs might have been caused by deficiency of protein. Eijkman therefore fed fowls on a diet with several kinds of sago, which was composed almost exclusively of carbohydrate. On the sago diet too the fowls became polyneuritic, but on a meat diet they remained healthy. Addition to a diet of polished rice of an amount of meat sufficient to make the total protein content of the mixture higher than that of crude rice did not prevent the beriberi-like signs in the fowls. In the course of his work Eijkman was astonished to find in experiments with potato starch that the birds did not show any sign of polyneuritis with that form of carbohydrate food (Eijkman, 1890).

The experiments just described contradicted the theory held at first by Eijkman, that the polyneuritic signs were caused by a toxic substance, present in the carbohydrate-rich food or produced from it by micro-organisms in the gut. He ascribed the fact that potato starch was not deleterious to its being less easily fermented in the gut, for he could demonstrate that rice starch was much more easily attacked by yeast than potato starch. It is, however, probable in the light of subsequent work that the protective action of the potato starch may have been due to its known tendency to cause a state of refection, in which growth is encouraged of the bacterial flora that produces B vitamins in the gut (Fridericia *et al.*, 1927; Kon and Watchorn, 1928).

By his first investigations Eijkman demonstrated that *polyneuritis gallinarum* depended on the kind of rice that was eaten by the birds. But he was not yet convinced that the mortal disease, human beriberi, could be explained in the same way. In the first article in which he described his experiments with fowls, Eijkman discussed the question whether his conclusions from his animal experiments could have any connection with the cause of beriberi in human beings. He summed up several ways in which *polyneuritis gallinarum* resembled human beriberi, especially in the degeneration of the peripheral nerves, but he concluded that no fact was known to compel the admission that beriberi had a connection with the diet as close as had been demonstrated for *polyneuritis gallinarum* (Eijkman, 1890).

Eijkman did not consider it allowable to make experiments with human beings, but the idea

occurred to him that perhaps a huge experiment had already been in existence for a long time without anyone being aware of it, for it was known that in some prisons beriberi was frequent, while others were almost free of it. Was it possible that in these human subjects also the frequency of beriberi had anything to do with the kind of rice that they consumed? Eijkman therefore asked his friend Dr. A. G. Vorderman, who, as an inspector of the civil medical service in Java had the medical supervision of the jails, to inquire into the frequency of beriberi in different prisons and into the kind of rice the prisoners consumed. The result of the investigation was clear-cut. In the jails where the prisoners themselves milled the rice, so that crude rice was eaten, only sporadic cases of beriberi were seen; in the jails where machine-milled, white, polished rice was supplied, there were 30 times as many cases of beriberi as in the jails provided with hand-milled rice (Vorderman, 1897; see also Eijkman, 1897*b*). Vorderman distinguished 3 kinds of rice: crude rice containing almost all the pericarp and germ, half-milled rice containing part of the pericarp and the germ, and white, polished rice from which all the pericarp and germ had been removed in the machine mills. Of 37 jails supplied with crude rice, 36 were free from beriberi, but in one there were some cases that had been transferred; of the 12 jails with half-milled rice, beriberi was found in 5, but in less than 1 per cent. of the inmates; of the 52 jails with polished rice, beriberi was present in 37 and in many of them scores of the inmates were affected.

Formerly, imported rice had been suspected of causing beriberi, but the researches of Vorderman showed that the degree of milling and not the origin of the rice was the important factor in connection with beriberi. In 1897 he found evidence also that crude rice was able not only to prevent but also to cure incipient beriberi. That consumption of machine-milled rice was the only causative factor in beriberi was proved in a certain prison in the village of Tulung Agung, where 5·8 per cent. of the prisoners were found with beriberi. After no change except replacement of the polished rice in the diet by crude rice, even without disinfection beriberi disappeared.

In 1896 Eijkman, who had been working very hard for 8 years in the tropics, went on leave to Europe and some years later he was appointed Professor of Hygiene at the University of Utrecht in Holland. Grijns, a young medical surgeon, was appointed by the Government of the Netherlands Indies to the laboratory in Batavia to continue Eijkman's investigations.

By the work of Eijkman, completed by that of Vorderman, it had become evident that *polyneuritis gallinarum* and beriberi in man were caused by a diet consisting predominantly of white, polished rice and that the disease could be prevented or cured by a diet containing crude rice if the morbid condition had not progressed too far. But in what did the deleterious influence of the polished rice consist? Eijkman was still inclined to think of a toxic substance, produced in the gut from the carbohydrate-rich food, probably by micro-organisms, a poison which could act on the nervous system, while the pericarp of the rice contained an antidote (Eijkman, 1897*a*).

Eijkman had shown (1893) by his rejection of the theory of "tropical anaemia", held for centuries, that he did not hesitate to accept the right conclusions from experimental data even when they were in contradiction to a generally accepted theory. Nevertheless he hesitated to abandon the simple, classical theory of nutrition, and tried to explain the established facts by a complex view. Some years later, when he had been compelled to change this view, he took as motto for a lecture "*simplex non veri sigillum*" (simplicity is no sign of truth) (Eijkman, 1913 *a*, *b*).

Grijns was commissioned by the Netherlands Indies Government to investigate the physiological and pharmacological properties of the tannin contained in unpolished, red rice and possibly of other constituents which might require to be considered in relation to the etiology of beriberi. It was not required that he should keep strictly to the letter of his commission, but that his investigation, by discovering the connection between diet and polyneuritis, should aim at getting an insight into the etiology of the neuritis which would make it possible to obtain rational control of the disease.

Grijns (1901) continued Eijkman's experiments with fowls. He began by studying the influence of the mineral salts present in the rice pericarp, and was able to demonstrate that the occurrence of polyneuritis in fowls fed entirely on polished rice could not be considered a result of salt starvation. He further proved that neither protein starvation nor mineral starvation could be the cause of polyneuritis. In contradiction to the view originally held by Eijkman, Grijns showed that the development of polyneuritis was not connected with a particular kind of starch in the diet, for buffalo meat autoclaved at 120° C. for 2 hours produced polyneuritis in fowls. This last experiment excluded the possibility that the polyneuritis could be caused by infected food.

Grijns tested on fowls some substances known to be helpful in beriberi in man. When *katjang idjoe*, the name in Java for the green bean of *Phaseolus radiatus*, was added to the diet the birds were protected against polyneuritis.

In his first publication describing experiments conducted since 1896, after discussing all the

former theories on the cause of beriberi, Grijns (1900) came to the conclusion that very little was known about the metabolism of the peripheral nervous system but, from the comparatively small extent of the blood supply to the nerves, a low metabolic rate might be assumed. If, further, for the maintenance of the peripheral nervous system a certain substance or group of substances was indispensable, but was not indispensable for the metabolism of muscles, it might be assumed that the amount necessary was very small. We cannot therefore, be surprised that such substances had hitherto escaped detection by chemical analysis. Thus Grijns was the first scientist who clearly expressed the theory that in food there occur in small quantities unknown organic substances, essential for health. He called them protective substances. Casimir Funk afterwards coined the name " vitamine " for them, because the supposed antineuritic vitamine, which he believed that he had isolated, proved to be an amine (Funk, 1911 ; 1914). It has since become clear that Funk did not isolate the antiberiberi but the antipellagra vitamin, nicotinic acid, and that several members of the new class of substances were not amines at all. Drummond (1920) later proposed to drop the terminal e and call them vitamins, a proposal which has been adopted generally.

Grijns went on leave in 1904 and for the first years after his return, by the orders of a new chief, his activities were confined to routine work. Some years later he had the opportunity to resume research and repeated the experiments of Eijkman designed to discover an infectious origin of fowl polyneuritis. With de Haan he demonstrated the absence of specific antibodies in the blood in human beriberi and in fowl polyneuritis (Grijns and de Haan, 1909). The results of all his attempts to obtain evidence that fowl polyneuritis is an infectious disease or is caused by toxins were negative and were in accordance with his theory of the absence of protective substances from the diet. Grijns attempted to isolate the protective substance first from *katjang idjoe*, the green bean of *Phaseolus radiatus*, and later from *dedek*, the rice polishings containing the pericarp and germ obtainable from the rice mills (Grijns, 1935). Soon afterwards, when he had just obtained a fine new laboratory, his health, after a long stay in the tropics, forced him to return to Europe.

Beriberi is seen mostly in regions where polished rice is the staple food of the population. In countries where people consume very large quantities of other highly milled cereals, beriberi may occasionally occur. The nearly exclusive consumption of highly milled wheat was found to cause beriberi in Newfoundland, when poor fishermen sold their fish in order to buy the pure white wheaten flour (Little, 1912 ; see also Aykroyd, 1930). Holst (1911–12) showed that beriberi occurred among Norwegian sailors consuming a great deal of white bread baked from wheaten flour or wheat and rye flour in equal proportion.

Confirmation and Extension of the Work of Eijkman and Grijns

Braddon (1909) in Malaya recorded that thousands of Tamils, natives of Southern India, migrated yearly to Malaya while still greater numbers of Chinese had been pouring into the same region. In conditions of toil, fatigue, exposure, influence of climate and place, there was no single condition affecting the Chinese to which the Tamil was not equally exposed. Of 16,716 cases of beriberi admitted to the Government hospitals, 16,325 or 97·5 per cent. were Chinese and 0·5 per cent. were Tamils. The Tamils were consumers of cured (parboiled) rice, the Chinese never ate cured rice but only polished rice. So it was obvious that the white, polished rice caused beriberi, and that cured rice was innocuous. Braddon came to the conclusion that the presence of a poison in white, polished rice could explain all the phenomena of beriberi.

Between 1906 and 1908 Fraser and Stanton watched the effect of white rice compared with that of parboiled rice in the diet of about 300 Javanese coolies engaged in road construction in a remote part of the district of Negri Sembilan in the Malay States, described as " virgin jungle ". Rice accounted for about 60 per cent. of the calories in the food supplied, which was the same for all the workers, except that different groups working in different places received either white rice or parboiled rice. Among 273 coolies receiving parboiled rice no case of beriberi occurred ; among 220 receiving white rice 20 developed the disease, but could be cured when parboiled rice was substituted in their diet. Subjects consuming parboiled rice did not contract the disease when in contact with beriberi patients. It was concluded that beriberi in the Malay Peninsula " has, if not its origin, at least an intimate connection with white rice " (Fraser and Stanton, 1909).

Vedder in his book on beriberi (1913, p. 144) wrote : " I have been authoritatively informed that Fraser and Stanton, in the course of their work on beriberi, performed a large number of human experiments, in which they tried by every conceivable method, including insect transmission, to infect healthy individuals from beriberi patients. These experiments were all negative, but were unfortunately suppressed by the Government for political reasons."

Fletcher conducted trials from 1905 to 1908 in the Kuala Lumpur Lunatic Asylum to test the

three following theories of the causation of beriberi: the theory of place-infection; the theory of contagion and of transmission by parasites such as bugs and lice; and the dietetic theory, which included as possible causes nitrogen starvation and presence of a poison in rice. To test the dietary theory, he divided the patients into two groups, one of which was given the best quality of white, polished rice obtainable, while the other had cured (parboiled) rice. All other food and conditions were the same for both groups. In connection with the theory of place-infection, it is interesting to note that in a ward which had been a "hot-bed of beriberi" and was later occupied for 18 months by patients having a cured rice diet, not a single case of beriberi occurred during the whole of that time. Of 219 patients receiving cured rice, not one was attacked by beriberi; at the start of the experiment, 4 were already suffering from beriberi, but during the trial they were restored to health. Of 226 patients receiving polished rice, 65 were attacked by beriberi. From this experiment Fletcher concluded that "white polished rice, although of the best quality, is a cause of beriberi, acting either by some poison which it contains or by a starvation due to some defect in the nutritive value of such rice" (Fletcher, 1909).

Distribution of the Antineuritic Substance

Cooper (1912; 1914), working in the Lister Institute in London, investigated the amounts of different raw foodstuffs which were sufficient to prevent polyneuritis for a definite period in pigeons fed on polished rice. For the prevention of beriberi he recommended egg yolk, heart muscle, liver, nuts, barley and lentils as suitable foodstuffs with which to supplement a polished rice diet. In 1914 Braddon and Cooper, working in the same Institute, wrote: "It is now taken as definitely settled that the disease beriberi is essentially privatory in origin, resulting from a deficiency in the food supply of a substance or substances the precise nature of which is at present unknown" (Braddon and Cooper, 1914). They further demonstrated that the absolute amount of antineuritic material required by the organism depended on the total calorie value of the diet, and in particular was increased with increase in the proportion of carbohydrate.

First Attempts to isolate the Antineuritic Substance

When Grijns had come to the conclusion that the preventive and curative action of crude, unpolished rice must be ascribed to an unknown chemical substance or substances present in the outer layers (silverskin) of the rice grain, he tried to isolate this material. He began his experiments with *dedek*, the offal from the steam-powered rice mills, which contains a mixture of silverskin and germ. He worked also with extracts of several kinds of bean which, in his experiments with fowls, had been shown to contain the protective substance. He was unable, however, to achieve very thorough fractionation (Grijns, 1935).

Hulshoff Pol (1907) extracted *katjang idjoe* beans with water, precipitated the solution with basic lead acetate, removed the lead from the precipitate with sulphuric acid and evaporated the filtrate. By this procedure he obtained a more or less crystalline substance which he called "X-acid", but the preparation was far from pure and 1 g. was required to cure *polyneuritis gallinarum*.

The most important work on isolation was that of Funk (1911; 1913; 1914) working at the Lister Institute in London. He succeeded in isolating a crystalline substance which was active in curing polyneuritis in pigeons. As is shown later (p. 8), the cure of these pigeons is not an absolute criterion of the antineuritic value of a preparation. As already mentioned, Funk coined for this substance the name of vitamine, because his substance was chemically an amine and considered to be essential for life (*cf.* under "Nomenclature", p. 10).

Hofmeister (1920) in Strasbourg extracted rice polishings with acidulated 80 per cent. alcohol. The solution, after purification and removal of the fats, was treated with potassium bismuth iodide, the precipitate was freed from choline and treated with Ag_2CO_3, and the silver was eliminated by HCl or H_2S. He obtained deliquescent, slightly red-coloured crystals which were active in curing polyneuritis in pigeons in doses of from 5 to 10 mg.

The Japanese investigators Suzuki, Shimamura and Odake (1912) treated an extract of rice bran with phosphotungstic acid. The precipitate was decomposed with barium hydroxide and acidified with sulphuric acid, and the filtrate was evaporated under reduced pressure. By further fractionation with tannic acid and picric acid, a more or less crystalline mass was obtained of the picrate of "oryzanine", as the Japanese workers called their antineuritic substance. It was active in a dose of 10 mg. daily. Drummond and Funk (1914) could not confirm the Japanese results.

R. R. Williams, working in the Bureau of Chemistry in the Philippine Islands, made several efforts to isolate the antineuritic substance (Chamberlain, Vedder and Williams, 1912). In earlier work Chamberlain and Vedder (1911), working in the same Bureau of Chemistry in Manila, had described their chemical investigation of a neuritis-preventing extract of rice polishings, and proved that the neuritis-preventing principle was soluble in cold water and in cold 95 per cent. alcohol, was dialysable and was adsorbed by bone

black or animal charcoal. By experiments with fowls the phosphate, the inorganic salts and the sucrose contained in this extract were shown to be inactive, but the workers then concluded that: "A preliminary examination showed that the extract was of so complex a nature as to render a direct search for the neuritis-preventing substance impracticable". After adsorption on animal charcoal the active principle could not be removed from the charcoal by elution with water, absolute alcohol or ether.

Isolation of a Pure Crystalline Antineuritic Vitamin

When I went to Java in the beginning of 1917 I had the good luck to work in the newly built, large laboratory of the Dutch East Indian Medical Service. There I met Grijns who, however, soon had to return to Holland because of ill health. At that time we knew already from the first attempts to isolate the protective substance that it was not a protein, that it was dialysable and therefore had a relatively small molecule, and that it was probably an organic base. We knew further that the *dedek* or rice bran, the mixture of pericarp and germ from the steam-powered rice mills, was a good source of the unknown substance.

I found that extraction of *dedek* with water acidulated with 3 per cent. hydrochloric acid gave a solution that cured polyneuritic fowls; 30 per cent. alcohol was usually added for protection against bacteria and moulds. Water and alcohol were evaporated below 50° C. and by experiments with fowls it was proved that almost all of the protective substance was present in the extract.

It had been found, however, by several investigators, that if an injection with a certain extract is followed by a temporary cure of polyneuritis in fowls, it affords no evidence that the extract contains the vitamin. Thus Eijkman and van Hoogenhuyze (1916) found that injection with a solution of potassium and sodium chloride brought about a temporary cure, at least with pigeons, and Theiler, Green and Viljoen (1915) found that injection even of sterilised water had a similar effect. In experiments expressly undertaken for the purpose, I was able fully to confirm these observations.

As long as the vitamin was not isolated we were dependent on the biological method and had to use prophylactic and not curative tests. It seemed that the biological method might be improved in two ways, thereby making it less dependent on circumstances and more accurate.

The first way was to seek as criterion some milder sign which might be evident before the outbreak of manifest polyneuritis. It might be possible that some such sign could be found, appearing after the fowl had been fed on polished rice for some time, but disappearing promptly and specifically after administration of the protective substance. In order to find such signs, it would be necessary to study closely changes in metabolism and in the composition of the body fluids. An additional result of such an inquiry might be perhaps to give a better knowledge of the nature of beriberi and might eventually lead to the discovery of methods of detecting human beriberi before it manifested itself clinically, so that measures might be taken to arrest the disease in its early stages. As far as I had been able to discover in the literature, this subject had been studied only sporadically and almost nothing had been reported.

There was, however, one statement in the literature that encouraged me to make further experiments, the discovery by Ramoino (1916) that the respiratory quotient of fowls fed on polished rice was considerably below normal. Dr. Mangkoewinoto and I were not, however, able entirely to confirm this result. The respiratory quotient on a diet of polished rice was sometimes low but the fall was not constant and was, therefore, not suitable as a criterion for diagnosing early polyneuritis (Jansen and Mangkoewinoto, 1920).

A second way to improve the biological method would be to discover some animal much more susceptible than fowls to lack of the antineuritic vitamin, and liable in consequence to sicken more quickly and more consistently. Rice-birds (*Padda oryzivora*), used by Ottow (1915), did not fulfil these conditions; sometimes there was an even longer period than with pigeons before signs of illness appeared and, in addition, individual differences were much greater. Many other small Javanese birds failed to show any greater susceptibility. In the end, however, in bondols or *nonnetjes* (*Munia maja*) I found a species of bird which is much more susceptible than fowls. The latter, when fed on polished rice showed no manifest sign of polyneuritis after several weeks, but not one of the scores of bondols that were kept on the same food remained healthy for longer than 12 days; they usually developed polyneuritis within 10 days. Moreover they are very small, weighing only about 12 g., so that 10 could be kept in one cage. The signs of polyneuritis were just as characteristic as with fowls or pigeons. If a bondol with incipient polyneuritis was allowed to fly, it generally did so in circles. On feeding the birds on crude rice a speedy and complete recovery generally occurred. Another advantage of these small birds was that they required less of any material to be tested. From 1920 all tests for estimating the content of protective substance present in the many fractions obtained from rice polishings were made by feeding bondols on a

basal diet of polished rice, supplemented with the fraction to be tested for its vitamin content [1] (Jansen, 1920).

The different kinds of polished rice obtainable in the market at Batavia were not all quite free from the protective substance so, in preparing our basal diet, we first washed the rice for 24 hours in running water to remove the last traces of pericarp. We found that the vitamin content of the rice was thus reduced to a constant low amount. After drying, 2 per cent. of a mixture of inorganic salts (Osborne and Mendel, 1913) and 0·25 per cent. of cod liver oil were added to the dry rice.

My chief, Dr. W. T. de Vogel, Director of the Netherlands Indies Health Service, and his successor, Dr. van Lonkhuyzen, both encouraged research, and the latter put the necessary funds at my disposal when the work grew more extensive and larger equipment became necessary. About that time Dr. Donath joined me and we were able to train as technicians several Javanese and Chinese young men, who very ably and industriously helped us. In the end we were able to extract the *dedek* in vessels holding a cubic metre of extracting fluid and to obtain every week the extract from 100 kg. of *dedek*. This extract contained all the active substance from the *dedek*, but also much, about 20 kg., of impurities. Seidell (1916) had already demonstrated that the vitamin could be selectively adsorbed by Lloyd's reagent, a variety of fuller's earth. We tried the different kinds of fuller's earth that could be obtained in Java and in the end succeeded in adsorbing the vitamin on a fuller's earth called "acid clay", obtained from Cheribon in Java.

The extract from 100 kg. of *dedek* was diluted to 300 litres, brought to p_H 4·5 and stirred by an electric stirrer with 3 kg. of acid clay. Experiments with bondols showed that most of the vitamin was adsorbed. To extract the vitamin from the acid clay, it was treated with baryta at p_H 12 to 13. As the vitamin had proved to be unstable in alkaline solution, elution had to be performed at a low temperature, by adding ice to the baryta solution and working as speedily as possible. Elution was therefore made with small portions directly passed into cold dilute sulphuric acid. In that way an acid fluid was obtained containing about 100 g. dry material and retaining 80 per cent. of the activity of the original 100 kg. of *dedek*, nearly a 1000-fold concentration. For the further purification we were much helped by the work of scientists who had tried to purify extracts and especially by Barger's monograph on *The simpler natural Bases*, which had recently been published (Barger, 1914). In Chapter 8 of this book several methods were outlined for the isolation of these bases. As there were indications that the vitamin we were seeking was perhaps such a base we tried to fractionate the filtrate from the acid clay, using several of these methods one after another, and each time determining, by tests with bondols, in which precipitate or filtrate the greater part of the vitamin was present. We thus obtained substances in which the activity per mg. became higher and higher. We used silver sulphate and baryta, phosphotungstic acid, platinic chloride and picrolonic acid. Other methods suggested by Barger were tried also, but gave no improvement. When the fraction was almost chemically pure, we obtained nice crystals by treatment with gold chloride.

The first precipitate obtained with platinic chloride, after decomposition, gave a substance with such great activity that all of 10 bondols remained healthy for 23 days when the washed white rice diet was enriched with 8 μg. per 2 g., which was the quantity of rice eaten daily by a healthy bondol. When the vitamin was obtained pure, it was found that a bondol needed 2 μg. of it daily. The solids of the platinic chloride fraction, therefore, contained about 25 per cent. of the vitamin. The preparation could be further purified by crystallisation from alcohol and acetone, and at last we obtained about 100 mg. of a chemically pure substance with m.p. 253° C. Recrystallisation did not give a higher melting-point or greater activity in the bondol test. The results of experiments with pigeons confirmed the antineuritic activity of the crystals we had isolated (Jansen and Donath, 1926).

As soon as we were convinced that the isolated crystals were the protective substance or vitamin itself, we sent some scores of milligrams to Utrecht, to Professor Eijkman, the originator of the idea that beriberi is caused by the lack of a substance which is present in the pericarp of rice. Eijkman (1927) confirmed in preventive and curative experiments on pigeons and cocks that the crystals were antineuritically active, and that addition of from 2 to 4 mg. per kg. to white polished rice was sufficient to restore its antineuritic activity. After congratulating us, Eijkman wrote that he was astonished that so small a quantity of a pure chemical substance was active. He himself and many others had come to the opinion that protection against polyneuritis and beriberi was not due to one substance but to a mixture of two or more because, in all former attempts to purify the active extracts, the workers came at last to a point where further purification seemed to destroy the activity. Eijkman was now, however, convinced that his

[1] When I met J. C. Drummond after my return to Europe he told me that after my first publication of the suitability of *Munia maja* for this type of experiment, he tried to obtain some in London, but the price was prohibitive, about £1 a pair. In Batavia we paid a halfpenny for one.

former opinion was wrong and that all the antineuritic activity was present in one pure chemical substance.

In the Medical Laboratory at Batavia a micro-apparatus for making an elementary analysis was available and with it we obtained for the purified crystalline hydrochloride the empirical formula $C_6H_{10}ON_2HCl$; the formula was confirmed by analysis of the crystalline gold double salt, but at that time the presence of sulphur in the molecule was missed.

The preparation of the pure antineuritic vitamin had been a very expensive process, and the product was much too costly for use in prevention of human beriberi. The Medical Laboratory in Batavia, therefore, issued three preparations for combating human beriberi. The first consisted of acid clay that had been activated by treatment with the crude extract from rice polishings. This powder was pressed into tablets of 0·25 g., 4 of which contained the vitamin from 30 g. of *dedek*. The results of animal experiments showed that the activated acid clay yielded its vitamin to the alkaline contents of the intestines. In human beings it proved to be equally active.

For use in infantile beriberi we prepared an extract from the activated acid clay, one ml. of which contained the vitamin corresponding to 300 g. of *dedek*; 0·1 ml. was, therefore, an adequate daily dose for a man. This small quantity has no influence on the taste of the food.

For the treatment of cardiac beriberi we prepared ampoules containing 1 mg. of the almost pure vitamin in solution. When a cardiac crisis of beriberi is heralded by precordial pain, palpitation and cyanosis, quick action is necessary, since the condition is responsible for most of the fatalities that occur in beriberi. After injection of the contents of an ampoule, patients who appeared to be at the point of death from cardiac failure were promptly and permanently relieved.

One of the cardinal signs of human beriberi, not seen in birds, is the pronounced tendency for accumulation of watery exudates or transudates, manifested in oedema. It is the principal sign by which beriberi is recognised by peoples where it is indigenous. By giving the tablets of the acid clay adsorbate prepared from rice polishings to patients with oedema from beriberi, it was found that this sign, too, soon disappeared.

Five years after our isolation of the pure vitamin from rice polishings Windaus and his collaborators in Göttingen isolated the pure, crystalline antineuritic substance from yeast (Windaus *et al.*, 1931). They demonstrated the presence of sulphur in the molecule and gave the tentative formula $C_{12}H_{17}ON_3S$. It took about four more years before three separate groups of investigators almost simultaneously achieved synthesis and the structural formula was established. The three groups of investigators were Williams and Cline (1936) at Rahway, Andersag and Westphal (1937) at Elberfeld, and Todd and Bergel (1937) in Edinburgh. The synthetic antineuritic vitamin proved to be identical with the crystalline material obtained from rice polishings or from yeast. The structural formula was found to be that of a pyrimidine ring linked by a methyl group to a thiazole ring. Synthetic hydrochlorides or nitrates of the antineuritic vitamin are now being produced cheaply in quantity and used to enrich polished rice. The milling industry, which had been responsible for the frequent occurrence of beriberi, is thus able now to combat the disease by restoring the substance originally removed from the crude rice in the milling process.

Nomenclature

We have seen that Funk introduced the name "vitamine" because he thought that the water-soluble substance isolated by him and supposed to be the antineuritic factor was an amine, and was essential for life.

Holst (1907) in Christiania (now Oslo) studied the ship beriberi of Norwegian sailors and found that it had signs like those of the beriberi seen in rice-eating countries, and other signs like those of the long known scurvy. Holst therefore travelled to Batavia to discuss the problem with Grijns, taking as experimental animals not birds but guineapigs. With his collaborator, Frölich, he had come to the conclusion from their experiments that guineapigs given a diet of polished rice developed a condition that was identical in all essentials with human scurvy (Holst and Frölich, 1907). The condition was not prevented or cured with rice polishings but with raw cabbage or other vegetables or fruits. So Holst predicated the existence of another essential substance, later the anti-scorbutic vitamin.

In 1909 Stepp had shown that a lipoid substance was essential for the existence of mice (Stepp, 1909; 1912). In 1913 McCollum and Davis showed that a fat-soluble accessory substance was essential for the growth of rats, and in 1915 that a water-soluble substance also was necessary (McCollum and Davis, 1913; 1915). It was proposed to call the two factors fat-soluble A and water-soluble B (McCollum and Kennedy, 1916).

Thus by 1920 three different vitamins had been recognised of which two were not amines at all but, since the name "vitamine" had come into general use, Drummond (1920) suggested that the final e should be dropped. His suggestion found general acceptance, so that now this new class of physiologically important substances is everywhere known as vitamins.

It was a lucky chance that the Far-Eastern investigators of polyneuritis worked with birds that got polyneuritis in a few weeks on a diet of polished rice. If they had used rats or other mammals, it would have taken much longer to find the cause of polyneuritis since rice has many other deficiencies. In the course of their experiments Eijkman and Grijns had often seen what they called " croupous inflammation of the nasal and pharyngeal cavities and of the eyes", which later proved to be xerophthalmia from lack of vitamin A (Grijns, 1935). American and English investigators worked chiefly with rats as experimental animals, and on a rice diet the rats died from other deficiencies before showing signs of neuritis. It thus became obvious that in nature there were other water-soluble vitamins besides the antineuritic vitamin. Distinction was, therefore, made between the antineuritic, heat-labile vitamin B_1 and a heat-stable vitamin B_2. Later, when many other water-soluble vitamins had been found, the name vitamin B complex was introduced.

Even before vitamin B_1 was isolated, many names had already been given to it, oryzanine by Suzuki and his colleagues (Suzuki *et al.*, 1912), toruline by Edie and his colleagues (Edie *et al.*, 1912) and antineuritine by Hofmeister (1920). In 1937, when many other B vitamins had already been isolated, I proposed the name " aneurine ", which was adopted in several European countries. In the United States, however, there was opposition because the name aneurine was an abbreviation of antineuritic vitamin and, therefore, perhaps suggestive of a therapeutic substance, such names being forbidden by the Council on Pharmacy and Chemistry. The workers in Merck's team, at Rahway, who had synthesised vitamin B_1, therefore suggested the more purely chemical name " thiamine ", to indicate that the vitamin is a sulphur-containing substance.

At the International Physiological Congress in 1938 at Zürich, an afternoon was devoted to discussing the name to be adopted internationally for the antineuritic vitamin, but without result. After the Second World War the Commission on the Nomenclature of Biological Chemistry of the International Union for Pure and Applied Chemistry, at its session in New York in 1951, unanimously adopted the name " thiamine ".

Historical Survey of Events

1873 Van Leent was apparently the first to conclude that the type of diet had something to do with the origin of beriberi. By reducing the ration of rice in the diet of the sailors in the Dutch navy, he was able to eradicate beriberi almost entirely from the warships (van Leent, 1880).

1883 Takaki independently produced the same results in the Japanese navy (Takaki, 1887; 1906).

1890 Eijkman proved that *polyneuritis gallinarum* depended on the kind of rice the birds were given to eat. Consumption of white polished rice caused polyneuritis ; on crude rice the fowls remained healthy (Eijkman, 1890).

1896 Vorderman, after a survey of Javanese prisons at Eijkman's request, stated that human beriberi depended on the kind of rice eaten, in the same way as *polyneuritis gallinarnm.* Eijkman and Vorderman therefore concluded that a diet of cooked, steam-milled, polished rice was the cause of human beriberi (Vorderman, 1897).

1900 Grijns, continuing the work of Eijkman, decided that *polyneuritis gallinarum* was caused by a partial hunger, that is to say, a deficiency of a protective substance. He began experiments to isolate such a substance from beans or rice polishings, and proved that the hypothetical antineuritic substance was destroyed by autoclaving (Grijns, 1901 ; 1935).

1911 Funk, believing he had isolated the pure antineuritic substance, coined the name " vitamine " for it. About a quarter of a century later it was shown by Elvehjem and his colleagues that Funk's substance, nicotinic acid amide, was not the antineuritic but the antipellagra vitamin (Elvehjem *et al.*, 1937). Funk stated his opinion that besides beriberi there were other nutritional deficiency diseases, such as scurvy, pellagra and rickets, which might perhaps be due to a deficiency of the antineuritic substance or of other vitamines (Funk, 1912).

1926 Isolation of the chemically pure, antineuritic substance by Jansen and Donath (1926).

1929 R. A. Peters and his collaborators demonstrated that the head retraction and opisthotonus of pigeons fed on polished rice were of central and not of peripheral nerve origin, and that vitamin B_1 played a special part in the metabolism of carbohydrates and in tissue oxidations (Kinnersley and Peters, 1929 ; Gavrilescu and Peters, 1931 ; Peters, 1936).

1931 Adoption of the activity of 10 mg. of activated acid clay as the international unit for vitamin B_1 by the Health Organisation of the League of Nations (League of Nations, 1931).

1936 Chemical method for estimating vitamin B_1 by the thiochrome reaction described by Jansen (1936).

1936–37 Determination of the structure, and synthesis, of vitamin B_1, almost simultaneously by Williams and Cline (1936), Todd and Bergel (1937) and Andersag and Westphal (1937).

1937 Identification by Lohmann and Schuster (1937) of the pyrophosphoric ester of vitamin B_1 with cocarboxylase, the coenzyme of carboxylase, which is the enzyme involved in the decarboxylation of pyruvic acid in the metabolism of carbohydrates.

1938–40 Adoption of the activity of 3 μg. of pure synthetic vitamin B_1 chloride hydrochloride as the international unit for vitamin B_1 by the Health Organisation of the League of Nations (League of Nations, 1938 ; 1940).

1943 Allowance of thiamine recommended as about 0·5 mg. per 1000 Cal. of the diet by the Food and Nutrition Board of the National Research Council in Washington (National Research Council, U.S.A., 1943).

1946 Enrichment of milled rice (Williams-Waterman Fund, 1950).

1949 Investigation in Bataan (Philippine Islands) of the influence of enriched rice on beriberi (Food and Agriculture Organization, 1954).

1951 Adoption of the name thiamine by the Commission on the Nomenclature of Biological Chemistry of the International Union for Pure and Applied Chemistry.

Conclusion

From the historical summary just given we see how long it took before the new idea of essential trace nutrients in nutrition was accepted and before its consequences were given practical application.

During the period of the researches on thiamine many other vitamins were discovered and the whole picture of the science of nutrition became changed. At the moment we know that for correct nutrition at least fifty nutrients are required in balanced proportions, and that we are not yet at the end of the list. Since the Second World War tables have been drawn up of recommended dietary allowances for some of these nutrients.

Education in applying this newer knowledge of nutrition has conferred great benefits on the health of humanity. The most spectacular effects have been seen in the United Kingdom where, during the second world war, the government sought and accepted the advice of nutritional experts on how to maintain satisfactory nutrition for the whole population within the limitations of the necessary system of food supply and distribution, with the consequence that during the war the state of health of the civil population improved considerably in spite of war-time difficulties. We cannot, however, say even now that the nutrition of the Western civilised countries is perfect. Very few persons in those countries go through life without dental disease and we become more and more convinced that imperfect dentition depends on our modern food (see, *e.g.*, Sognnaes, 1949). It is known that aborigines who change their primitive type of diet to include modern, refined foodstuffs pay for the change with deterioration of their teeth. Probably traces of certain nutrients (mineral salts and perhaps organic nutrients) play a part in the caries-producing nature of the diet (Wynn *et al.*, 1953).

The life expectation of the Western nations has increased considerably in the last half century, a change probably due largely to improvement in the diet. Nevertheless, a man who in these days has reached the age of seventy years has not so very many more years to live than his septuagenarian grandfather of half a century ago. There are signs that the quantity and quality of the diet are important in old age, but gerontology is a chapter in the science of nutrition which is only now beginning to be written. Many nutrition workers hold the opinion that the so-called degenerative diseases, particularly arteriosclerosis and hypertensive cardiovascular disease, are connected with faulty nutrition.

So we see that, although the idea of the need for trace nutrients in our food has taken several decades to gain recognition from scientists and the medical profession, it has already led to a great improvement in the health of the nations, and there is still room for much research before all the fruits of the idea can be harvested.

2

GRÜNWALD, H. Skleněný rozprašovač. [**An all-glass sprayer.**] *Chem. listy*, 1955, **49,** 1235. [Biol. Inst. ČAV, Prague.]

A glass sprayer of simple construction, which is easy to clean and permits regulation of the size of the drops of spray, is described.

A. Jančařik (Czechoslovakia).

3

PŘISTOUPIL, I. Jednoduchý rozprašovač pro chromatografii. [**A simple sprayer for chromatography.**] *Chem. listy*, 1955, **49,** 136. [Inst. Haematol., Prague.]

4

SOLMS, J. Kontinuierliche Papierchromatographie. [**Continuous paper chromatography.**] *Helv. chim. Acta*, 1955, **38,** 1127–1133. [Agrik. Chem. Inst., Techn. Hochsch., Zürich.]

An apparatus is described in which the developing solvent flows down the surface of a paper cylinder rotating about a vertical axis and the mixture to be analysed is applied to the surface at a fixed position. The eluates are collected in a series of stationary receivers. The procedure has been applied to mixtures of lithium and potassium chlorides, xylose and galactose, and methylene blue and fuchsin.—H. G. Bray.

5

WILLIAMS, F. G. (Jr.), PICKELS, E. G. and DURRUM, E. L. **Improved hanging-strip paper-electrophoresis technique.** *Science*, 1955, **121,** 829–830. [Specialized Instruments Corp., Belmont, Calif.]

An apparatus and a technique for paper electrophoresis are described which prevent distortion of the pattern on drying and give a high degree of reproducibility.—H. G. Bray.

6

MARHA, K. and JENŠOVSKÝ, L. Automatický registrační fotometr. [**Automatic recording photometer.**] *Chem. listy*, 1955, **49,** 926–929. [Inst. Work Hyg., Prague.]

ANALYTICAL METHODS

General

7

LINDNER, K. Anwendung von Mischfarben bei Titration farbiger Lösungen. [**Use of neutral colours in the titration of coloured solutions.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **102,** 37–39. [Staat. Inst. Ernährungswiss., Budapest.]

To avoid difficulties in the titration of coloured solutions, the use of non-interfering dyes of the complementary colour is suggested. As an example the estimation by titration with 2 : 6-dichlorophenolindophenol of ascorbic acid in tomatoes, rose hips, beetroot and pink potatoes is discussed; the dyes used are solutions of Patentblau A (Schultz No. 827) and Lichtgrün R (Schultz No. 765), 0·1 or 0·01 g. dye per 100 ml. water. Recovery of added ascorbic acid was accurate within 3 per cent.

W. M. Deans.

8

NARAYANAN, E. K. and MENON, P. S. **A method for partition chromatography using paper of uniform water saturation.** *Indian J. Med. Res.*, 1955, **43,** 359–363. [Central Res. Inst., Kasauli.]

Paper strips kept horizontally over parallel strips of wet fabric in a sealed measuring cylinder attained uniform water saturation. Partition coefficients calculated from this method support the theory of Consden *et al.* (*Biochem. J.*, 1944, **38,** 224) that separation of substances on paper is due to partition rather than adsorption. The method is recommended for the estimation of standard R_F values.—A. Hepburn.

9

CARLES, J. Nouvelle technique de chromatographie circulaire. [**New circular chromatography technique.**] *Bull. Soc. Chim. biol.*, 1955, **37,** 521–524. [Lab. Veg. Physiol., Inst. Catholique, Toulouse.]

10

BELL, J. M. **A comparison of peroxide- and oxygen-bomb calorimetry of feedstuffs.** *Canad. J. Agric. Sci.*, 1955, **35,** 366–370. [Dept. Animal Husb., Univ. Saskatchewan, Saskatoon.]

The corrections which are necessary for data obtained by the 2 methods of bomb calorimetry are considered. Values are given for 16 samples

analysed with both types of equipment; they included maize starch, cereal grains, mixed feeds and faeces from both ruminant and non-ruminant animals. Results for the peroxide- were consistently higher than for the oxygen-bomb calorimeter. Conditions other than proportion of ash to organic matter may influence the findings but, from these results and taking the oxygen method as standard, covariance analysis of percentage error by the second method with percentage ash gave a correlation coefficient which was significant. A regression equation was calculated which gave a good agreement between values after adjustment of the peroxide-bomb data. Further investigation with feeds high in ash content may be necessary.

D. Harvey.

Carbohydrate Constituents

11

JONES, J. K. N. **Chemistry of the carbohydrates.** *Annu. Rev. Biochem.*, 1955, **24,** 113–134. [Dept. Chem., Queen's Univ., Kingston, Ont.]

12

MÜLLER, K. and TÄUFEL, K. Die Reversion der Saccharide und ihre Bedeutung für die Analytik der Kohlenhydrate. 2. Konstitutionelle und analytische Betrachtungen. [**The reversion of sugars and its importance in analysis of carbohydrates. 2. Constitutional and analytical considerations.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **100,** 437–441. [Inst. Ernährungsforsch., Potsdam-Rehbrücke.]

For part 1 see Abst. 4534, Vol. 25.

A number of disaccharides, *e.g.*, trehalose, maltose, cellobiose, gentiobiose, are formed when a concentrated solution of glucose is heated with HCl. To avoid reversion during hydrolysis in analytical procedures the concentration of the saccharide in the hydrolysis mixture should not exceed 1 per cent.—H. G. Bray.

13

FORIST, A. A. and SPECK, J. C. (Jr.) **Ceriometric determination of sugars.** *Anal. Chem.*, 1955, **27,** 1166. [Kedzie Chem. Lab., Michigan State Coll., E. Lansing.]

Two procedures are described for the detection of small changes in sugar concentration. The sugars are oxidised by ceric perchlorate and the excess reagent is removed by addition of oxalate or arsenite; the excess of the latter is titrated with ceric perchlorate, with nitro-ferroin as indicator.

H. G. Bray.

14

DISCHE, S. **Colour production and stability in the Folin and Wu method of blood glucose estimation.** *J. Clin. Pathol.*, 1955, **8,** 253–261. [R.A.F. Inst. Pathol. Trop. Med., Halton, Aylesbury, Bucks.]

Conditions, *e.g.*, concentration of phosphomolybdate reagent, temperature, affecting density of colour are discussed. A simplified modification of the original procedure in which fading is obviated is described.—H. G. Bray.

15

RAYMOND, P. Détermination du saccharose et du lactose dans le chocolat. [**Estimation of sucrose and lactose in chocolate.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1955, **46,** 246–250. [Lab. N.V.P. de Gruyter en Zoon, Bois-le-Duc, Holland.] German and English summaries.

The chocolate is clarified with potassium ferrocyanide and zinc hydroxide. The filtrate is treated with an alkaline copper reagent; cuprous oxide is precipitated, separated and dissolved in nitric acid and Cu is estimated by titration with disodium ethylenediaminetetra-acetate, using murexide as indicator. The optical rotation of the filtrate is measured before and after acid hydrolysis. From these observations the sucrose and lactose contents can be calculated.—H. G. Bray.

16

GROSS, D. **Paper electrophoresis of polyhydric alcohols.** *Nature*, 1955, **176,** 362–363. [Res. Lab., Tate and Lyle, Ltd., Ravensbourne, Westerham Rd., Keston, Kent.]

Paper electrophoresis at high voltage enabled several mixtures of polyhydric alcohols and sugars to be separated. Examples given are the separation of dulcitol, mannitol, sorbitol and erythritol, and separation of the latter 3 from mannose, fructose, glucose and sorbose.—A. Hepburn.

17

CERBULIS, J. **Paper chromatography of sugar alcohols and their glycosides.** *Anal. Chem.*, 1955, **27,** 1400–1401. [Stephen F. Whitman and Son, Inc., Philadelphia 5, Pa.]

The solvent mixture used is a mixture of *n*-propanol, ethyl acetate and water (7 : 1 : 2) and the detecting reagent *p*-anisidine, which on heating gives white spots against a light brown background. R_F values are given for a number of polyols.

H. G. Bray.

18

KENNEDY-RIPON, A. J. and MAPES, R. E. A. **The examination of commercial sorbitols, with special reference to their suitability for diabetic diets.** *Analyst*, 1955, **80,** 568. [Frank Cooper, Ltd., Botley Rd., Oxford.]

Sorbitol produced by the reduction of starch hydrolysates contains starch and glucose. A copper reduction method is described in which precipitated cuprous oxide is isolated and estimated

by titration with permanganate. The tables of Sichert and Bleyer (*Ztschr. anal. Chem.*, 1936, **107,** 328) are used for the calculation of glucose, maltose and dextrin content.—H. G. Bray.

THALER, H. Das Filtrieren der Rohfaser. [**Filtration of crude fibre.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1955, **46,** 251–254. [Deutsch. Forschungsanst. Lebensmittelchem., Munich.] French and English summaries.

The fibre is filtered through a glass crucible containing a pad of filter paper pulp. Fat is removed by washing with organic solvents.—H. G. Bray.

Nitrogenous Constituents

20

DIXON, J. P. **The determination of microgram quantities of organic nitrogen.** *Anal. chim. Acta*, 1955, **13,** 12–15. ["Shell" Research, Ltd., Thornton Res. Centre, Chester.] French and German summaries.

A modified Kjeldahl procedure is described. The ammonia removed by steam distillation is estimated by reaction with hypobromite, the excess of which is estimated iodimetrically. Nitro-, nitroso- and azoxy-compounds and phenylhydrazines are treated with hydriodic acid and red phosphorus before digestion.—H. G. Bray.

21

BEAUCHENE, R. E., BERNEKING, A. D., SCHRENK, W. G., MITCHELL, H. L. and SILKER, R. E. **The quantitative estimation of amino nitrogen by determination of bound copper with the flame photometer.** *J. Biol. Chem.*, 1955, **214,** 731–739. [Kansas Agric. Exp. Stat., Manhattan.]

A washed copper phosphate suspension was added to an amino-acid solution or protein hydrolysate in a centrifuge tube, the excess reagent was removed by centrifuging and the supernatant fluid was analysed for amino-N by flame photometer with a standard copper curve. A number of plant materials and 16 amino-acids were studied. The method compared well with a spectrophotometric method modified from that of Woiwod (Abst. 4350, Vol. 19), and was more rapid.—A. Hepburn.

22

KAINZ, G. and SCHÖLLER, F. Über den Anwendungsbereich der Aminostickstoffbestimmung mittels salpetriger Säure. [**The range of applicability of the estimation of amino-nitrogen with nitrous acid.**] *Hoppe-Seyler's Ztschr.*, 1955, **301,** 259–268. [2. Chem. Lab., Univ. Vienna.]

An investigation was made of the behaviour of compounds which give high or low results in the Van Slyke amino-N estimation. Deamination by low and high concentrations of nitrite was studied and the causes of the discrepancies are discussed.—H. G. Bray.

23

33

YEOMAN, W. B. **The estimation of protein in cerebrospinal fluid using the M.R.C. photometer.** *J. Clin. Pathol.*, 1955, **8**, 252. [Dept. Pathol., Frenchay Hosp., Bristol.]

The Medical Research Council grey wedge photometer was found to be suitable for the turbidimetric estimation of protein in cerebrospinal fluid and for other procedures in which comparison with standard protein tubes is normally necessary.

H. G. Bray.

34

ROHRLICH, M., ADLER, G. and KRAMM, O. Versuche zur chemischen Differenzierung der Eiweiss-stoffe des Weizens und Roggens. 1. Untersuchungen der Eiweiss-stoffe mit Natriumhypochlorit. [**Chemical differentiation of the proteins of wheat and rye. 1. Studies of the proteins with sodium hypochlorite.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **102**, 85–97. [Versuchsanst., Getreideverwertung, Berlin.]

A manometric method is described for the measurement of the carbon dioxide and nitrogen evolved when proteins are treated with hypochlorite. The effect of the salt concentration of the medium and of the presence of different anions and cations on the reaction was studied. Results are given for the reactions of different proteins and protein fractions and for the effect of heat on the sensitivity of proteins to hypochlorite.—H. G. Bray.

35

SCHNEIDER, G. and SPARMANN, G. Über die Trennung von Pflanzenproteinen mit Hilfe der Hochspannungs-Papierelektrophorese. [**Separation of plant proteins by high-tension paper electrophoresis.**] *Naturwissenschaften*, 1955, **42**, 391. [Bot. Inst., Justus Liebig Hochsch., Giessen.]

With a borate buffer of *p*H 11·5 and a potential difference of 1500 volts, separation of protein fractions in plant materials can be achieved in 1·5 to 3 hr.—H. G. Bray.

36

GROSS, D. **Paper electrophoresis of amino-acids and oligopeptides at very high potential gradients.** *Nature*, 1955, **179**, 72–73. [Res. Lab., Tate and Lyle, Ltd., Ravensbourne, Westerham Rd., Keston, Kent.]

The potential gradient used is 130 to 200 volts per cm. Results obtained with this technique are illustrated. The chief advantage is the reduction of the time necessary for separation, *e.g.*, 30 min. for basic amino-acids and 8 to 15 min. for the preliminary separation of some amino-acids.

H. G. Bray.

37

HOLEYŠOVSKÝ, V. Š. F. O aminokyselinách a peptidech. 15. Preparativní isolace některých aminokyselin z hydrolysátu želatiny. [**Amino-acids and peptides. 15. Preparation of some amino-acids from gelatine hydrolysates.**] *Chem. listy*, 1955, **49**, 243–248. [Inst. Org. Chem. ČAV, Prague.]

Pure optically active amino-acids, L-proline, DL-hydroxyproline, L-valine, and a mixture of leucine and *iso*leucine, were prepared from gelatine hydrolysates by a modification of Fischer's method of distillation and chromatography on a cellulose column.—A. Jančařik (Czechoslovakia).

38

MUELLER, G. C., BOWMAN, G. and HERRANEN, A. **Desalting amino acid solutions by ion exchange.** *Anal. Chem.*, 1955, **27**, 1357–1358. [McArdle Mem. Lab., Med. Sch., Univ. Wisconsin, Madison.]

Amino-acids and cations are adsorbed together on the hydrogen form of Dowex 50 and most of the amino-acids are then eluted free from salts with 0·8 *N* HCl in 55 per cent. ethanol. By the procedure described 15 amino-acids were recovered quantitatively, and others by a modification of the method. The process was successfully applied to perchloric acid extracts of rat tissues.—H. G. Bray.

39

KRISHNAMURTHY, K. and SWAMINATHAN, M. **Quantitative determination of amino acids by circular paper chromatography.** *Anal. Chem.*, 1955, **27**, 1396–1399. [Central Food Technol. Res. Inst., Mysore.]

A procedure for the separation of 16 amino-acids by means of 5 different solvent mixtures is described.—H. G. Bray.

40

BARROLLIER, J. Ein Ninhydrinreagenz für quantitative Aminosäurebestimmungen auf Papierchromatogrammen. [**A ninhydrin reagent for quantitative estimation of amino-acids in paper chromatograms.**] *Naturwissenschaften*, 1955, **42**, 416. [Hauptlab. Schering A.G., West Berlin.]

The reagent consists of 75 mg. cadmium chloride, 6 ml. water, 0·3 ml. glacial acetic acid, 100 ml. acetone and 2 g. ninhydrin, combined in that order. It keeps well, but should be changed when a pink colour appears.

Paper chromatograms with up to 2×10^{-7} moles amino-acid per sq. cm. paper are soaked in the reagent and hung at room temperature for 24 hr. The dye can be extracted with methanol for colorimetry, or estimated on the paper (Barrollier, *Naturwissenschaften*, 1955, **42**, 126). The absorption maximum for all amino-acids except proline and hydroxyproline is 509 mμ.—D. Duncan.

41

CIFONELLI, J. A. and SMITH, F. **Detection of amino acids on paper chromatograms.** *Anal. Chem.*, 1955, **27**, 1501–1502. [Dept. Agric. Biochem., Univ. Minnesota, St. Paul.]

Some amino-acids which are not easily distinguished by the usual methods of one-dimensional chromatography, *e.g.*, glycine and serine, threonine and alanine, valine and methionine, may be identified by the procedure described. Dried chromatograms are treated with periodate and then with benzidine or starch-iodide reagents under different conditions. Mixtures of *tert.*-amyl alcohol, *n*-propanol and water are recommended as second solvents (after phenol) in two-dimensional chromatography, or in one-dimensional chromatography.

H. G. Bray.

BURMA, D. P. and CHAKRABORTTY, H. C. **Effect of the distance moved by the solvent on the R_F values in circular chromatography.** *Anal. chim. Acta*, 1955, **13**, 248–252. [Bose Res. Inst., Calcutta.] French and German summaries.

If the chromatography chamber is completely saturated the R_F values of amino-acids in phenol-water and butanol-acetic acid-water systems are independent of the distance travelled by the solvent.—H. G. Bray.

43

SUBRAMANIAN, N. and LAKSHMINARAYAN RAO, M. V. **A simple buffered solvent system for the two-dimensional paper chromatography of amino acids.** *J. Sci. Indust. Res. India*, 1955, **14**C, No. 2, 56–58. [Central Food Technol. Res. Inst., Mysore.]

44

KRAUT, H., KOFRÁNY, E., TELSCHOW, H. and WEBER, M. Aminosäurebestimmung in Nahrungsmitteln durch Chromatographie am Stärkesäulen. [**Estimation of amino-acids in foods by chromatography on starch columns.**] *Hoppe-Seyler's Ztschr.*, 1955, **301**, 165–184. [Abt. Ernährungsphysiol., Max-Planck-Inst. Arbeitsphysiol., Dortmund.]

The application of the Moore and Stein procedure to foods was investigated. The values obtained for the amino-acids in 6 materials had a mean deviation of $\pm$ 4·5 per cent. It was possible to account for 95 to 98 per cent. of the amino-N in casein and milk hydrolysates and for 90 to 95 per cent. in wheat flours and barley.—H. G. Bray.

45

IYER, G. Y. N. **Estimation of free amino acids in normal human plasma by paper-chromatography.** *Indian J. Med. Res.*, 1955, **43**, 189–193. [Med. Coll., Trivandrum.]

Of free amino-acids in human plasma, alanine, glutamic acid, glutamine, glycine, serine and tyrosine were separated on one paper chromatogram and *iso*leucine, leucine, phenylalanine and valine on another. The acids were estimated by colorimetric examination of the spot eluates.

A. Hepburn.

46

GORBACH, G., DEDIC, G. and PHILIPPI, E. H. Zur Bestimmung von freien Aminosäuren in biologischem Material. [**Estimation of free amino-acids in biological material.**] *Hoppe-Seyler's Ztschr.*, 1955, **301**, 185–190. [Inst. Biochem. Technol. Lebensmittelchem., Tech. Hochsch., Graz.]

The efficiency of precipitation of casein, blood fibrin, egg albumin and edestin from aqueous solutions containing free amino-acids by several precipitants was studied. Phosphomolybdic acid precipitated all the proteins almost quantitatively, while the amino-acids remained in solution. Phosphotungstic acid was almost as efficient in precipitating proteins and did not affect amino-acids. Calcium fluoride, sodium tungstate and trichloroacetic acid were less effective as protein

precipitants and still did not precipitate amino-acids.—H. G. Bray.

47

WISEBLATT, L. and MCCONNELL, W. B. **The estimation of β-hydroxy amino acids by a micro-diffusion method.** *Canad. J. Chem.*, 1955, **33,** 1452–1453. [Prairie Reg. Lab., Nat. Res. Counc. Canada, Saskatoon, Sask.]

The sample is treated in the outer chamber of a Conway microdiffusion unit with periodic acid, glycine and metaborate; the inner chamber contains a solution of boric acid. The ammonia liberated is estimated by titration of the contents of the inner chamber after 5 hr. In control experiments recoveries of serine ranged from 99·7 to 100·4 and of threonine from 99·5 to 100·3 per cent. Hydroxylysine, glucosamine and ethanolamine give ammonia under the conditions described.—H. G. Bray.

HERB, S. F. **Application of ultraviolet spectrophotometry to the analysis of fats and derivatives.** *J. Amer. Oil Chem. Soc.*, 1955, **32,** 153–158. [E. Reg. Res. Lab., Philadelphia, Pa.]

A review in which the present status, applications and limitations of the more commonly used methods are discussed.—G. A. Garton.

54

STÄHLI, H. Über die Bestimmung der Jodzahl. [**Estimation of iodine number.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1955, **46,** 121–162. [Lab. ASTRA Fett- und Ölwerke, Steffisburg.] French and English summaries.

A critical examination of several methods. The most reliable results were obtained by the use of a modified Wijs solution.—H. G. Bray.

55

GODFRAIN, J. C. Une méthode sinacide de dosage de la matière grasse du lait utilisant le matériel Gerber. [**A method without acid for the estimation of fat in milk using the Gerber material.**] *Rev. Méd. vét., Toulouse*, 1955, **106,** 370–372.

Milk is shaken in a butyrometer with a mixture of detergents, amyl alcohol and Scarlet R and placed in a water-bath at 100° C. for 6 min. After centrifuging and heating for 5 min. at 70° C., the fat globules form a pink layer which is easily seen in the butyrometer.—A. Hepburn.

56

SALWIN, H., BLOCH, I. K. and MITCHELL, J. H. (Jr.) **Rapid determination of fat in meat products.** *J. Agric. Food Chem.*, 1955, **3,** 588–593. [Quartermaster Food and Container Inst. Armed Forces, Chicago, Ill.]

A modified Babcock procedure is described in which a mixture of perchloric and acetic acids is used for digestion of the sample and separation of a clear fat column. An estimation takes about 30 min. Results obtained agree with those obtained by the dry solvent technique recommended by the Association of Official Agricultural Chemists (" Official Methods of Analysis ", 7th ed., 1950, p. 359).—H. G. Bray.

57

HART, P. C. Onderzoekingen omtrent de zachtheid van bacon. 1. Methoden van onderzoek en plaats van bemonstering. [**Studies on the softness of bacon. 1. Methods of investigation and place of sampling.**] *Landbouwk. Tijdschr.*, 1955, **67**, 420–426. [Inst. Veeteeltk. Onderzoek T.N.O.] English summary.

Hardness, or softness, of fat is judged by prodding with the thumb. For chemical investigation fat is extracted from the fatty tissue with light petroleum or, more rapidly and with several samples being processed at one time, in an autoclave at 138° C. and steam pressure of 2·25 atmospheres. After the fat is dried, iodine number and thiocyanate number are estimated. Representative samples are to be got 45 to 65 cm. from the fore end of the side. Shoulder fat is less saturated than back fat in general.—I. Leitch.

58

BEL'KEVICH, V. I. Novyi metod kolichestvennogo opredeleniya zhira v tkanayakh nasekomykh. [**A new method for the estimation of fat in insect tissues.**] *Zool. Zh.*, 1954, **33**, 709–713. [Moscow Stat. Plant Protection.]

59

ŠKODA, J. and ŠLECHTA, L. Acidobutyrometrické stanovení tuku v tukotvorných kvasinkách. [**Acidobutyrometric estimation of fat in fat-producing yeasts.**] *Chem. listy*, 1955, **49**, 1097. [Fac. Food Tech., Chem.-Tech. Univ., Prague.]

60

TROËNG, S. Oljehaltsbestämning i svenskt oljeväxtfrö. Ny gravimetrisk seriemetod utarbetad vid Cereallaboratoriet, Sveriges Utsädesförening, Svalöv. [**Estimation of oil in Swedish oilseeds. New gravimetric routine method from the Cereal Laboratory, Swedish Seed Association, Svalöv.**] *Kungl. Lantbruksakad. Tidskr.*, 1955, **94**, 125–140. English summary.

The ground sample was shaken mechanically in a centrifuge tube containing benzene and steel balls; it was then centrifuged and part of the benzene solution was removed by pipette, evaporated and weighed. The method was calibrated with known amounts of oil. Reproducibility was good and the difference from a continuous extraction method did not exceed 0·28 per cent. oil.

A. Hepburn.

61

CRUZ AUÑON, F. Estudio analitico del insaponificable de los aceites de algodon y de soja y su aplicacion a la investigacion de los mismos, solos y en sus mezclas. [**Analytical study of the unsaponifiable matter from cottonseed and soya bean oils and its application to the investigation of these oils, alone and in mixtures.**] *Bol. Inst. Nac. Invest. Agron., Madrid*, 1955, **15**, 187–239. [Inst. Fom. Prod. Fibras Textiles, Serv. Algodon, Seville.]

A method is described for analysing soya and cottonseed oils by chromatography on a silica column. The unsaponifiable fractions were isolated. They were characteristic of the oils, and could be used to estimate the proportion of each oil in a mixture.—T. D. Bell.

62

PERILÄ, O. **Separation of saturated straight chain-fatty acids. Qualitative paper chromatography.** *Acta chem. scand.*, 1955, **9**, 864–865. [Inst. Technol., Helsinki.]

The application of techniques due to a number of authors is described. R_F values are given for fatty acids from formic to cerotic acid.

H. G. Bray.

63

VAN DE KAMER, J. H., GERRITSMA, K. W. and WANSINK, E. J. **Gas-liquid partition chromatography: the separation and micro-estimation of volatile fatty acids from formic acid to dodecanoic acid.** *Biochem. J.*, 1955, **61**, 174–176. [Central Inst. Nutrit. Res. T.N.O., Utrecht.]

The gas-liquid chromatographic method of James and Martin (Abst. 77, Vol. 22) was modified to effect separation of acids from C_1 to C_{12} in one process. This is achieved by gradually raising the column temperature from 100° to 150° C. in such a way that 137° is reached when heptanoic acid has been titrated and 150° is reached after octanoic acid has left the column.—G. A. Garton.

64

INOUYE, Y., NODA, M. and HIRAYAMA, O. **Paper chromatography of unsaturated fatty acid esters as their mercuric acetate addition compounds.** *J. Amer. Oil Chem. Soc.*, 1955, **32**, 132–135. [Biochem. Lab., Coll. Agric., Kyoto Univ., Japan.]

Mercuric acetate addition compounds of the methyl esters of unsaturated fatty acids were separated and identified by reversed-phase paper,

chromatography; diphenylcarbazone (phenylazoformic acid phenylhydrazide) was used to detect the compounds on chromatograms.

The qualitative application of the method to the analysis of the component unsaturated acids of natural fats showed the presence of hitherto undetected tetradecenoic acid in olive oil and hexadecenoic acid in linseed oil.—G. A. Garton.

65

VAN DER VIES, J. **Determination of free non-volatile fatty acids.** *Biochem. J.*, 1955, **60,** 671. [Dept. Pharmacol. Res., N.V. Organon, Oss, The Netherlands.]

Plasma, 2 ml., is run into 6 ml. of phosphoric acid solution (metaphosphoric acid 50 g., NaCl 250 g. and water to 1 litre) contained in a 100-ml. flask. After a few minutes 16 ml. ethanol containing 0·4 per cent. amyl alcohol is delivered into the flask, followed by 20 ml. light petroleum. After shaking for 1 min. and allowing to stand, the light petroleum extract is filtered. Ten ml. of the extract is evaporated on a water bath, dried *in vacuo* and dissolved in 5 ml. neutral ethanol containing 0·6 mg. thymol blue per 100 ml. The fatty acids are then titrated with 0·01 *N* NaOH under a stream of N_2.—G. A. Garton.

66

JARRIER, M. and POLONOVSKI, J. Méthode de dosage des acides gras estérifiés et son application au sérum sanguin. [**Method for estimating esterified fatty acids and its application to blood serum.**] *Bull. Soc. Chim. biol.*, 1955, **37,** 495–499. [Lab. Chim. Biol., Fac. Méd., Paris.]

Esters are extracted from serum with alcohol-ether, the solvent being then removed by evaporation. The residue is treated with an ethanolic solution of hydroxylamine hydrochloride and the hydroxamate formed is estimated from the colour given with ferric perchlorate.—H. G. Bray.

67

FRANKEL, E. N. and TARASSUK, N. P. **An extraction-titration method for the determination of free fatty acids in rancid milk and cream.** *J. Dairy Sci.*, 1955, **38,** 751–763. [Dept. Dairy Indust., Univ. California, Davis.]

Fatty acids are extracted with ethanol, ether and light petroleum. Aliquots of the extract are titrated with alcoholic KOH using phenolphthalein as indicator. The method gives 95 to 100 per cent. recovery of added higher (C_{16}–C_{18}) fatty acids but only 52 to 58 per cent. of lower (C_4–C_8) acids. The effect of this error on the results obtained is considered. The distribution of the hydrolysis products of fat is discussed.—H. G. Bray.

68

GLOPPE, K. E. and HVIDSTEN, H. **Determination of volatile fatty acids in silage by distillation and by chromatographic methods.** *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 129–134. [Inst. Animal Nutrit., Royal Agric. Coll., Norway.]

Values are given for the formic, acetic, propionic and butyric acid content of 30 samples of silage estimated by the chromatographic method of Nijkamp (*Chem. Weekblad*, 1949, **45,** 480; 1950, **46,** 37) and for the acetic and butyric acid content of 17 of the samples estimated by a distillation method (Behrens, *Ztschr. angew. Chem.*, 1926, **39,** 1350). The agreement is good. The loss of volatile acids on drying potato silage is discussed.

H. G. Bray.

69

BAER, E. **Chemistry of the phosphatides.** *Annu. Rev. Biochem.*, 1955, **24,** 135–156. [Banting and Best Dept. Med. Res., Univ. Toronto.]

70

LEA, C. H., RHODES, D. N. and STOLL, R. D. **Phospholipids. 3. On the chromatographic separation of glycerophospholipids.** *Biochem. J.*, 1955, **60,** 353–363. [Low Temp. Res. Stat., Univ. Cambridge.]

For previous parts see Abst. 3884, Vol. 23; Title 4090, Vol. 24.

Good separations of natural and synthetic glycerophosphatides were obtained by using silica-impregnated paper with 20 per cent. (v/v) methanol in chloroform as developing solvent. Ninhydrin, phosphomolybdic acid/stannous chloride, fuchsin/sulphur dioxide and iodine vapour were used as detecting reagents. The preparation of pure phosphatidylethanolamine, lecithin, lysophosphatidylethanolamine and lysolecithin from normal and venom-treated eggs was achieved by using methanol-chloroform chromatography on a silicic acid column.—H. G. Bray.

71

SPERRY, W. M. and BRAND, F. C. **The determination of total lipides in blood serum.** *J. Biol. Chem.*, 1955, **213,** 69–76. [Dept. Biochem., New York State Psychiat. Inst.]

Serum or plasma, 1 ml., is pipetted into a 25-ml. volumetric flask containing 8·3 ml. methanol, and about the same volume of chloroform is added. The mixture is boiled, cooled to room temperature and made up to the mark with chloroform. The filtered extract, 20 ml., is then purified by the removal of non-lipid contaminants using one or other of 2 diffusion techniques. The purified lipid extract is dried and transferred to a tared 5-ml. volumetric flask. Weight of lipids × 125 = concentration in mg. per 100 ml. For further

analytical work on the extracted lipids it is necessary to store the weighed lipids in a desiccator containing pure nitrogen, to prevent oxidative degradation of cholesterol.—G. A. Garton.

72

HANEL, H. K. and DAM, H. **Determination of small amounts of total cholesterol by the Tschugaeff reaction with a note on the determination of lathosterol.** *Acta chem. scand.*, 1955, **9**, 677–682. [Dept. Biochem. Nutrit., Polytech. Inst., Copenhagen.]

The method is applicable to as little as 0·004 mg. per ml. cholesterol, the accuracy being about 3 per cent. Coprosterol gives a faint reaction under the conditions described, but dihydrocholesterol and epicholestanol do not react. Lathosterol (Δ-7-cholestenol) gives a yellow colour with maximum absorption at 395 mμ. and negligibly little at 528 mμ., the absorption maximum for the red colour given by cholesterol, so that the two may be estimated simultaneously.—H. G. Bray.

Other Organic Constituents

73

CARROLL, K. K. **Ion-exchange chromatography in alcohol.** *Nature*, 1955, **176**, 398–400. [Collip Med. Res. Lab., Univ. W. Ontario, London.]

Absolute alcohol could be used as an eluting agent in the separation of organic acids by ion-exchange chromatography. Acids with a high R_F value were eluted more readily when alcohol replaced water; those with a low R_F were retarded. The extension of this technique to include acids and bases with limited solubility in water seems promising.—A. Hepburn.

74

MCARDLE, B. **A modified method for the microdetermination of citric acid.** *Biochem. J.*, 1955, **60**, 647–649. [Clin. Res. Unit, Guy's Hosp., London, S.E.1.]

An improvement of the colorimetric method of Taylor (Abst. 3896, Vol. 23) applicable to 10 to 80 μg. citrate in biological fluids.—A. Hepburn.

75

HESS, W. C. and WHITE, A. A. **A simplified method for the determination of citric acid in dentin and bone.** *J. Dent. Res.*, 1955, **34**, 462–465. [Dept. Biol. Chem., Sch. Med., Georgetown Univ., Washington, D.C.]

76

TÄUFEL, K. and POHLOUDEK-FABINI, R. Zur Bestimmung der Citronensäure im Wein. [**Estimation of citric acid in wine.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **102**, 28–32. [Inst. Ernährungsforsch., Potsdam-Rehbrücke.]

77

BONTING, S. L. **The colorimetric determination of lactic acid in submicrogram quantities.** *Arch. Biochem. Biophys.*, 1955, **56**, 307–317. [Dept. Physiol., Coll. Med., State Univ. Iowa, Iowa City.]

This is an ultramicro adaptation of the method of Barker and Summerson (Abst. 831, Vol. 11). From 0·025 to 0·25 μg. lactic acid can be estimated in 25-μl. samples with a standard deviation of 0·0051 μg. The optimum conditions for a number of experimental variables have been established.

A. Hepburn.

78

KIELHÖFER, E., AUMANN, H. and SPECHT, M. Die colorimetrische Bestimmung der Äpfelsäure in Wein, Obstwein, Traubensaft und Obstsaft. [**Colorimetric estimation of malic acid in wine, fruit wine, grape juice and fruit juice.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **100**, 449–458. [Weinforschungsinst., Trier.]

The method depends on the reaction between malic acid and α-naphthol in concentrated H_2SO_4. The reagent is not specific for malic acid and the reaction with other substances was studied. In certain materials direct estimation of malic acid is possible, but in others it is necessary first to separate the acid by means of an ion-exchange resin (Permutit E 3). In both procedures malic acid is isolated as its barium salt, which is then treated with the reagent. After development of the red colour the mixture is centrifuged and the optical density of the supernatant fluid is measured.

H. G. Bray.

SMIT, C. J. B., JOSLYN, M. A. and LUKTON, A. **Determination of tannins and related polyphenols in foods. Comparison of Loewenthal and Pro methods.** *Anal. Chem.*, 1955, **27,** 1159–1162. [Dept. Food Technol., Univ. California, Berkeley.]

A comparison was made between methods depending on permanganate titration and colorimetric phosphomolybdic-tungstate reduction. It is concluded that both are highly empirical.

H. G. Bray.

See also Abst. 216.

Inorganic Constituents

85

GORDON, H. T. and HEWEL, C. A. **Paper chromatography of alkali and alkaline earth cations.** *Anal. Chem.*, 1955, **27,** 1471–1474. [Dept. Entomol., Univ. California, Berkeley.]

A simple apparatus for ascending one-dimensional chromatography is described. The developing solvent is a mixture of *iso*propanol, pyridine, water and acetic acid (8 : 8 : 4 : 1) and detection is by means of 8-hydroxyquinoline and uranyl zinc acetate. R_F values are given for a number of cations and organic compounds. Procedures are described for the concentration of dilute solutions before application to paper and for the precipitation of interfering anions by lead acetate directly on the paper strip.—H. G. Bray.

86

FRIEDMAN, H. S. and RUBIN, M. A. **Clinical significance of the magnesium : calcium ratio : technic for the determination of magnesium and calcium in biologic fluids.** *Clin. Chem.*, 1955, **1,** 125–133. [Chemo-Med. Inst., Georgetown Univ., Washington, D.C.]

An adaptation of the Schwartzenbach versene method (*Helv. chim. Acta*, 1946, **29,** 811), for the simultaneous estimation of Mg and Ca in serum and cerebrospinal fluid. The method may be applicable also to other body fluids.

A survey of 100 patients showed that the Mg : Ca molar ratio may be of clinical significance.

H. G. Bray.

87

QUENTIN, K. E. Calcium- und Magnesiumbestimmungen mit Natrium-äthylendiamintetraessigsäure unter besonderer Berücksichtigung der Mineralwässer. **[Estimation of calcium and magnesium with sodium ethylenediaminotetra-acetate with special application to mineral waters.]** *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **102,** 106–117. [Balneol. Inst., Univ. Munich.]

88

GORSUCH, T. T. and POSNER, A. M. **Colorimetric determination of micro quantities of calcium.** *Nature*, 1955, **176,** 268–269. [County Laboratories, Ltd., Stanmore, Middx.]

The murexide method of Ostertag and Rinck (*Chim. Anal.*, 1952, **34,** 108) is used at *p*H 6·2, but if the *p*H is increased to 11·0 the sensitivity of the reaction is increased at least fiftyfold, so that from 0 to 8 μg. Ca per 10 ml. can be estimated. Reference is made to the effect of other ions on the method.—H. G. Bray.

89

GEHRKE, C. W., AFFSPRUNG, H. E. and LEE, Y. C. **Direct ethylenediaminetetraacetate titration procedure for calcium in biological substances. Anion exchange separation of phosphate.**

Univ. Missouri Agric. Exp. Stat. Res. Bull. No. 570, October 1954, pp. 10.

Forage and feed samples were dry-ashed, dissolved in HCl and passed through an anion-exchange resin column to remove phosphate. Ca was then estimated directly by titration with disodium dihydrogen ethylenediaminetetra-acetate, with murexide as indicator. Recovery of added Ca was satisfactory. A significant error occurred only when the quantity of Ca in the solution to be titrated exceeded 20 mg. The method was more accurate than the accepted oxalate method and it has been applied to milk, urine, serum, rations, grains and other substances in which phosphate might interfere with the titration.—A. Hepburn.

90

BERGER, E. Y. **Calcium determination in biologic material.** *Clin. Chem.*, 1955, **1,** 249–252. [Res. Serv., Third (New York Univ.) Med. Div., Goldwater Mem. Hosp., Welfare Island, New York.]

Calcium is precipitated as its oxalate, which is oxidised with ammonium hexanitratocerate. The excess cerate is titrated with ferrous iron, with *o*-phenanthroline as indicator. The method is applicable to serum, heparinised plasma, urine, dried tissues and faeces.—H. G. Bray.

91

HORNER, W. H. (with LAWSON, N. L. and TRACHTENBERG, N. S.). **The determination of calcium in biologic material.** *J. Lab. Clin. Med.*, 1955, **45,** 951–957. [Dept. Metabol., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

A rapid photometric method with versene and murexide is described.—H. G. Bray.

92

MITCHELL, L. C. **Separation and identification of acids by paper chromatography. 1. The halides.** *J. Assoc. Off. Agric. Chem.*, 1955, **38,** 832–835. [Food and Drug Admin., Dept. Health, Washington 25, D.C.]

F, Cl, Br, I, Na and K ions are separated by a solution of ammonia in 2-methoxyethanol (methyl cellosolve) as developing solvent. The detecting reagent is ethanolic ammoniacal $AgNO_3$.

H. G. Bray.

93

WOOD, T. **A reagent for the detection of chloride and of certain purines and pyrimidines on paper chromatograms.** *Nature*, 1955, **176,** 175–176. [Res. Dept., Bovril, Ltd., 148–166 Old St., London, W.C.1.]

In chromatograms stained with a reagent containing bromophenol blue, acetone and $AgNO_3$, halogen ions and certain purine and pyrimidine compounds could be identified. It is suggested that the reagent may be generally applied to compounds forming an insoluble complex with silver.—A. Hepburn.

94

DOLE, V. P. and THORN, N. A. **Precise determination of chloride in plasma by differential potentiometric titration.** *Anal. Chem.*, 1955, **27,** 1184–1186. [Hosp. Rockefeller Inst. Med. Res., New York 21.]

The procedure described is applicable to 1-ml. samples and has a precision of 0·1 per cent. Two electrodes are used, one of which can be isolated by means of a sleeve between successive additions of silver nitrate.—H. G. Bray.

95

LUHMAN, C. A. **A rapid potentiometric method for the determination of soluble chlorine in feeds.** *J. Assoc. Off. Agric. Chem.*, 1955, **38,** 764–766. [California Dept. Agric., Sacramento.]

96

PETERSON, R. E. and BOLLIER, M. E. **Spectrophotometric determination of serum copper with biscyclohexanoneoxalyldihydrazone.** *Anal. Chem.*, 1955, **27,** 1195–1197. [Nat. Inst. Arthritis Metabol. Dis., Nat. Insts. Health, Bethesda, Md.]

Deproteinised serum is treated with the reagent at *p*H 7·5 to 7·9 and the optical density of the blue complex formed is measured at 600 mμ. The reagent is more sensitive than others commonly used and gives no colour with other ions occurring in biological material.—H. G. Bray.

97

ANDRUS, S. **Determination of copper in plant materials by means of zinc dibenzyldithiocarbamate.** *Analyst*, 1955, **80,** 514–516. [Dept. Chem., Nat. Agric. Advisory Serv., Trawscoed, Aberystwyth.]

The material is wet-ashed and the copper in the diluted digest is extracted with a solution of zinc dibenzyl dithiocarbamate in carbon tetrachloride; the optical density of the extract is measured at 440 mμ. Other metals occurring in plant material do not interfere.—H. G. Bray.

98

TANNER, H. and RENTSCHLER, H. Der Polarograph als Hilfsmittel für Getränkeanalysen. 2. Die quantitative polarographische Bestimmung von Kupfer in süssen und vergorenen Getränken. [**The polarograph as a means of analysing beverages. 2. Qualitative polarographic estimation of copper in sweet and fermented beverages.**] *Mitt. Geb. Lebensmittel.*

Hyg., 1955, **46**, 209–219. [Eidg. Versuchsanst., Wädenswil.] French and English summaries.

For part 1 see *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1953, **96**, 161.

99

SCHALL, E. D. and WILLIAMSON, H. G. **Spectrophotometric determination of fluoride.** *J. Assoc. Off. Agric. Chem.*, 1955, **38**, 454–459. [Dept. Biochem., Purdue Univ., Lafayette, Ind.]

The sample is ignited in the presence of magnesium acetate and the ash is dissolved in 60 per cent. perchloric acid. Chloride is precipitated with silver carbonate and fluoride is removed by distillation. The absorbance of the distillate is measured at 360 mμ. in a solution containing potassium titanium oxalate, ascorbic acid and a biphthalate buffer (pH 4·2).—H. G. Bray.

100

BARTLET, J. C., KAVANAGH, D. and CHAPMAN, R. A. **The determination of the fluoride content of edible bone meal.** *Canad. J. Technol.*, 1955, **33**, 348–355. [Food and Drug Labs., Dept. Nat. Health Welfare, Ottawa, Ont.]

A sample of bonemeal was ignited, dissolved in perchloric acid and distilled as fluosilicic acid into NaOH. Fluoride was estimated colorimetrically by its ability to bleach a solution of ferric salicylate. The standard error was 2·3 per cent. Although not so sensitive as other colorimetric methods, this procedure is rapid and the reagents are easily obtainable.—A. Hepburn.

101

DEUTSCH, S. **Overcoming the effect of manganese dioxide in fluoride determinations.** *Anal. Chem.*, 1955, **27**, 1154–1155. [Air Control Res. Dept., Kaiser Steel Corp., Fontana, Calif.]

Manganese dioxide and chloride in plant materials interfere with the modified method of Willard and Winter (*Anal. Chem.*, 1953, **25**, 450) for fluoride by liberating chlorine which may bleach the alizarin red indicator. Interference can be eliminated by the incorporation of 3 per cent. hydrogen peroxide in the distillation mixture.—H. G. Bray.

102

MARIANI-MARELLI, O. and MARIANI, A. La determinazione fotometrica dello jodio nelle sostanze organiche. [**Photometric estimation of iodine in organic substances.**] *Rend. Ist. Super. Sanità, Rome*, 1955, **18**, 225–231. [Lab. Chim.] French, English and German summaries.

The method depends on colorimetric estimation of iodine dissolved in carbon disulphide, and is especially suitable for estimating quantities of less than 1 mg.—D. Duncan.

103

SAMSON, M., BROWN, H. and EICHEN, S. **Cross-contaminator exclusion test for dry-ashing determination of protein-bound iodine.** *Clin. Chem.*, 1955, **1**, 269–272. [Dept. Res., Samson Labs., Philadelphia, Pa.]

In this method, with 1 drop of serum a concentration of over 400 μg. I per ml., which might interfere with the estimation of I by the dry-ashing technique (see Abst. 3912, Vol. 23), is detected qualitatively.—A. Hepburn.

106

SMITH, A. J. **A colorimetric method for the estimation of serum magnesium.** *Biochem. J.*, 1955, **60**, 522–527. [Dept. Chem. Pathol., King's Coll. (Univ. Durham), Newcastle upon Tyne.]

Calcium is precipitated as oxalate and the supernatant fluid is deproteinised with trichloroacetic acid. The filtrate has its pH adjusted to 10·1 and is treated with Eriochrome Black T and the optical density of the solution is measured at 520 mμ. In 12 control experiments 95 to 102 per cent. of added magnesium was recovered from serum. The values obtained for normal serum Mg, mean 2·1 mg. per 100 ml., fell within the ranges of normal values found by other workers with other methods.

H. G. Bray.

107

POLLEY, D. and MILLER, V. L. **Rapid microprocedure for determination of mercury in biological and mineral materials.** *Anal. Chem.*, 1955, **27**, 1162–1164. [State Coll. Washington, W. Washington Exp. Stat., Puyallup.]

108

RHODES, D. N. **Micro-determination of phosphorus.** *Nature*, 1955, **176**, 215–216. [Low Temp. Res. Stat., Univ. Cambridge.]

The method of Allen (*Biochem. J.*, 1940, **34,** 858) was modified, the molybdenum blue colour being developed in the digestion flask and extracted by means of methyl*iso*butylketone. The sensitivity of the method is increased tenfold.—H. G. Bray.

109

CAVELL, A. J. **The colorimetric determination of phosphorus in plant materials.** *J. Sci. Food Agric.*, **6,** 479–480. [Nat. Agric. Advisory Serv., West Midland Province, Wolverhampton.]

The ashed material is dissolved in HCl, the solution is treated with a mixture of ammonium molybdate and ammonium vanadate and the transmittancy of the mixture is measured at 400 mμ.—H. G. Bray.

110

DESIKACHAR, H. S. R. **A shortened procedure for routine assay of phosphorus in foodstuffs.** *J. Sci. Indust. Res. India*, 1955, **14**C, No. 1, 32–33. [Central Food Technol. Res. Inst., Mysore.]

In foodstuffs and a few biological materials P was estimated colorimetrically after digestion with H_2SO_4 for 5 min. and also after complete oxidation with H_2SO_4, HNO_3 and perchloric acid by the method of Gerritz (see Abst. 44, Vol. 5). The shortened procedure measured 95 per cent. of the total P and is suggested as a routine method for large numbers of samples when only comparative values are required. Added sucrose or partly oxidised egg albumin did not interfere with the colour development.—A. Hepburn.

111

GERRITSMA, K. W. and FREDERIKS, J. C. Scheiding en quantitatieve bepaling van gecondenseerde phosphaten met behulp van de papierchromatografie. [**Separation and quantitative estimation of condensed phosphates by chromatography on paper.**] *Chem. Weekblad*, 1955, **51,** 197–201. [Centraal Inst. Voedingsonderzoek T.N.O., Utrecht.]

Increasing use of inorganic phosphates in the food industry create a need for analytical methods to distinguish different P compounds. An alkaline and an acid developing fluid are used: 30 ml. propanol, 30 ml. ethanol, 39 ml. water and 1 ml. 25 per cent. ammonia; and 75 ml. *iso*propanol, 25 ml. water, 5 g. trichloroacetic acid and 0·3 ml. 25 per cent. ammonia. The spots are made visible by spraying with a phosphomolybdate complex and exposing to ultraviolet light.—I. Leitch.

112

ČERVENKA, R. and KOZLOVÁ, M. Polarografické stanovení selenu ve vodách. [**Polarographic estimation of selenium in water.**] *Chem. listy*, 1955, **49,** 1158–1161. [Hyg. Inst., Prague.]

A method for polarographic estimation of small amounts of selenium in water and in air is described. In dilute hydrobromic acid Se gives well defined polarographic waves.

A. Jančařík (Czechoslovakia).

113

BROEKHUYSEN, J. and BÉCHET, J. Microdosage du soufre dans les matériaux biologiques. [**Micro-estimation of sulphur in biological materials.**] *Anal. chim. Acta*, 1955, **13,** 277–280. [Serv. Recherche C.E.R.I.A., Inst. Émile Gryson, Brussels.] English and German summaries.

The material is oxidised in an oxygen bomb, yielding sulphate, which is precipitated as its barium salt. Excess Ba is precipitated as chromate at *p*H 9 and the excess chromate, which under the conditions described is equivalent to the sulphate originally present, is estimated colorimetrically at 370 mμ. By this method 0·1 mg. S can be estimated to within 2 to 3 per cent.—H. G. Bray.

114

KALINOWSKA, R. and SIEDLECKA, J. Oznaczanie małych ilości cynku. [**Estimation of small amounts of zinc.**] *Rocz. Państwowego Zakł. Hig.*, 1955, **6,** 93–107. [Zakł. Badania Żywności i Przedmiotów Użytku PZH.] Russian and English summaries.

Zinc was estimated colorimetrically after reacting with dithizone in an alkaline medium. Cu and Sn^{2+}, which interfere, were removed. Less than 1 μg. Zn could be estimated. The accuracy was within 10 per cent. with an average error of 5 per cent. (From English summary.)—A. Hepburn.

125

DANNACHER, S. and STAUB, M. Über die Bestimmung des Fleischgehaltes in Suppenpräparaten. [**Estimation of the meat content of soup preparations.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1955, **46,** 163–167. [Kanton. Lab., Zürich.] French and English summaries.

A method is described, based on estimation of the N content of the insoluble protein of the meat in the soup preparation, *i.e.*, the dried residue after extraction of fat with ether, and of salt with alcohol and water. If the meat used is also available, a simple calculation gives the meat content of the preparation. The residue should be examined under the microscope to test that it consists of meat fibres. Ingredients containing starch, *e.g.* potato flour, or protein, *e.g.* peasemeal, can be corrected for. Tests with chicken meat and chicken soup of known composition showed an accuracy of 1 per cent.

The insoluble protein content of " chicken meat" from different countries ranged from 45 to 70 per cent. of the dry matter, the difference being due chiefly to fat. The N content of the insoluble

protein of the meat had only the narrow range from 15·2 to 15·7 per cent., mean 15·5 per cent. The N content of the insoluble protein of single samples of oxtail and ham was almost the same. Hence it is suggested that not the meat content but a minimum amount of insoluble protein of meat of the particular kind should be legally prescribed.—W. M. Deans.

MICROBIOLOGICAL

128

LEES, K. A. and TOOTILL, J. P. R. **Microbiological assay on large plates. 1. General considerations with particular reference to routine assay. 2. Precise assay. 3. High throughput, low precision assays.** *Analyst*, 1955, **80,** 95–110; 110–123; 531–535. [Glaxo Labs., Ltd., Sefton Park, Stoke Poges, Bucks.]

These papers describe in detail, with statistical analysis, methods for microbiological assay on large seeded agar plates ranging in size from 12 to 18 in. square and accommodating from 64 to 144 tests on each, so that many samples with few replicates, or few samples with many replicates, can be dealt with simultaneously. Constancy of the volume of test solution applied is achieved by the use of insulating beads of unglazed porcelain. The first paper gives experimental designs suitable for routine assay of several samples simultaneously with a standard error of about $\pm$ 5 per cent., the second for more accurate assay, *e.g.*, of relatively pure preparations of antibiotics or growth substances, up to 3 samples simultaneously with a standard error of about 1 per cent., and the third for large-scale preliminary work, *e.g.*, on crude fermentation products, where over 10 samples may have to be assayed simultaneously but a standard error of $\pm$ 10 per cent. is immaterial.—W. M. Deans.

129

MERTZ, E. T., RENNERT, S. S. and COLE, E. W. **A bacterial method for determining protein digestibility.** *J. Nutrition*, 1955, **56,** 437–446. [Dept. Biochem., Purdue Univ., Lafayette, Ind.]

A method for the estimation of the digestibility of protein in which the proteolytic action of pepsin is combined with that of *Pseudomonas aeruginosa*. Some ether-soluble substances and dialysable sugars inhibit the action of *Pseudomonas* and must be removed from the feed before digestibility of protein is estimated. The particle size of the feed may also be of importance, and this is being investigated. Results obtained by the method described agreed within 10 per cent. with those obtained from trials with rats.—T. D. Bell.

PAYNE, M. A., LAZZARINI, A. A., BROT, N. and BEAL, J. M. **Preparation of colloidal fat suspensions for intravenous use.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 122–123. [Labs. Surg. Res., New York Hosp.-Cornell Med. Centre.]

One part of fat is dissolved in 10 parts absolute alcohol at 80° C. Pyrogen-free water, maintained at 80° C., is then added very slowly with constant agitation until the total concentration of alcohol is about 50 per cent. The alcohol is then evaporated on a water-bath, leaving the fat suspended in water. Dextrose or any salt in isotonic concentration may be added and the colloidal suspension may be sterilised by autoclaving in the container from which it is to be administered. The suspension has a particle size of 250 mμ.

Preliminary observations on a group of patients given 15 per cent. colloidal animal fat intravenously in amounts up to 500 ml. showed no reaction of any kind.—F. C. Aitken.

145

GEYER, R. P., OLSEN, F. R., ANDRUS, S. B., WADDELL, W. R. and STARE, F. J. **Preparation of fat emulsions for intravenous alimentation.** *J. Amer. Oil Chem. Soc.*, 1955, **32**, 365–370. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Descriptions are given of the homogeniser and auxiliary equipment used, the method of preparation of the emulsions and the routine animal tests made with each batch of emulsion.—F. C. Aitken.

CLARKE, P. M. **Nomograms for multiple slope-ratio assays arranged in blocks, and improved nomograms for assays without blocks.** *Brit. J. Pharmacol. Chemotherap.*, 1955, **10**, 296–304. [Nat. Inst. Res. Dairying, Univ. Reading.]

This paper presents approximate graphical methods for use in analysing the results of simple and multiple slope-ratio assays. The multiple assays are considered to be made in blocks, with a complete replication in each block. Each replication consists in single trials of each of the $(\nu - 1)$ test preparations at 2 non-zero levels, along with trials of a standard preparation at 2 non-zero levels, and a common zero dose. The last 3 treatments are repeated approximately $\sqrt{\nu - 1}$ times within each replicate. The simple assays consist in only 5 treatments, 2 levels of the test and of the standard preparation and a common zero dose, and no blocking is considered necessary.

Examples are given of the analytical lay-out. Estimates of error variance are obtained from ranges instead of by mean square analysis. The potencies of the test preparations relative to the standard are obtained by using nomograms, which also supply 95 per cent. fiducial limits, and these are shown to be very close to the results from exact analyses of the same data.

Data are supplied for the construction of nomograms for simple assays with any number of replications and for multiple assays of up to 15 different test preparations, arranged in 2 complete replicate blocks. Validity tests are given for all cases.—I. McDonald.

CANAWAY, R. J., RAYMOND, W. F. and TAYLOR, J. C. **The automatic recording of animal behaviour in the field.** *Electronic Eng.*, March 1955, pp. 4. [Grassland Res. Inst., Hurley, Berks.]

Electric switches at different points on the animal's body activate pins in contact with "Teledeltos" paper, making a continuous record of behaviour electrically. The switches and also the recording box, which includes clockwork-driven paper spools, batteries and relays, are mounted on leather harness worn by the animal. The box, size $6 \times 6 \times 4$ in., weighs 5 lb. A mercury switch on one leg counts each double movement, which is one complete walking cycle. A second switch, operated by the pressure of the animal's body, records lying and standing and a third switch operated by a cam mechanism from a loop arm resting on the neck records movements of the head up or down. Jaw movements with the head up represent rumination and with the head down, grazing. The problem of recording jaw movements has not yet been solved satisfactorily. The behaviour of a harnessed bullock was not adversely affected in comparison with that of its monozygous twin mate, and the records were in good agreement with detailed observations.

J. L. Corbett.

GONZÁLEZ, Q. J., ALVAREZ-BUYLLA, R. and AZPE, T. Nueva cámara metabolimétrica para pequeños animales de laboratorio. [**A new metabolism chamber for small laboratory animals.**] *An. Esc. nac. Ciencias biol.*, 1954,

8, 5–16. [Lab. Metabol., Esc. Nac. Ciencias Biol., I.P.N., Mexico.] English summary.

A description with photographs and diagrams is given of a glass respiration chamber suitable for use with small animals for measuring the rate and volume of respiration, CO_2 production and the respiratory quotient. Temperature records and electrocardiograms could be obtained at the same time.—A. M. Copping.

149

BRUNE, H. and SEIKA, E. Differenzierung von Qualitätsmerkmalen der Muskulatur des Schweines durch Quellungsversuche. [**Evaluation of quality of pork muscle by means of swelling tests.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 67–73. [Inst. Tierphysiol., Univ. Göttingen.]

Samples taken just after slaughter from the superficial gluteus muscle of 140 Improved Landschwein pigs of both sexes were classified as dark and firm or bright and soft and their behaviour in distilled water or hypertonic salt solutions was studied over a period of 10 hr. The 2 types of muscle differed in composition, the dark type having less fat and more water than the bright, but the differences could not fully explain their different behaviour on soaking. This was most clear in distilled water, in which the dark type steadily increased in weight, mainly by taking up water, but the bright steadily lost weight. The dark type lost less N to the water. The results are discussed and it is considered that a swelling test in distilled water would be useful in addition to practical judgement. The difference was not due to sex but there was nothing to show whether feeding or fatigue had anything to do with it.

LLOYD, L. E., RUTHERFORD, B. E. and CRAMPTON, E. W. **A comparison of titanic oxide and chromic oxide as index materials for determining apparent digestibility.** *J. Nutrition*, 1955, **56,** 265–271. [Dept. Nutrit., Macdonald Coll., McGill Univ., Que.]

Sixty rats, initially 60 days old, received a diet of 90 parts ground wheat and 10 parts of a protein and mineral supplement. For half the rats it contained 0·25 per cent. TiO_2 and for the rest 0·25 per cent. Cr_2O_3. Markers were estimated in the faeces.

Constant maximum excretion of TiO_2 was not attained in 6 days, though that of Cr_2O_3 was attained within 4 days. The coefficient of apparent digestion was always lower by the TiO_2 method than that found by the conventional time collection method, but with Cr_2O_3 the two values were identical. Total recovery of TiO_2 for 30 rats from the 7th to the 13th day was 92·0 per cent., that of Cr_2O_3 99·8.

It is concluded that Cr_2O_3 is better than TiO_2 as a marker in digestibility studies.—D. Duncan.

DOUGHERTY, R. W. **Permanent stomach and intestinal fistulas in ruminants: some modifications and simplifications.** *Cornell Vet.*, 1955, **45,** 331–357. [Dept. Physiol., New York State Vet. Coll., Ithaca, N.Y.]

This is an extremely useful paper describing the surgical techniques employed for cannulation of different parts of the alimentary tract of ruminants, and for exteriorising the flow of digesta. A full description of the method of making the cannulas or other forms of obturator used in ruminants is given, including the author's design for a large rubber stopper for large rumen fistulas in cattle. The article is unique in that it gathers together in one paper a lot of scattered information.

A. T. Phillipson.

152

NICHOLS, R. E. **A sampling tube for rumen fluid.** *Amer. J. Vet. Res.*, 1955, **16,** 410. [Dept. Vet. Sci., Wisconsin Agric. Exp. Stat., Madison.]

This tube consists of an inner and a closely fitting outer cylinder. Each has a large hole near the closed end. This end is inserted into the rumen with the outer tube turned so as to close the holes. When in place the inner tube is rotated through 180° and allowed to fill with fluid. The fluid is then trapped by rotating the inner tube through a further 180° and the sample is withdrawn in the tube.—A. T. Phillipson.

Lebensmittelfrischhaltung, Karlsruhe.]

For part 1 see *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **100,** 253.

Heating in 15 per cent. HCl at 112° to 179° C. under pressures up to 10 atm. causes 0·5 to 1 per cent. deamination of glycine, glutamic acid, valine, leucine, *iso*leucine, lysine, histidine and methionine. Addition of sucrose, 25 mg. per 100 ml., increases the extent of decomposition to about 2 per cent. Up to 47 per cent. of cystine, cysteine, serine and arginine is decomposed. Only with arginine and cysteine does sucrose increase this. Glycylglycine is more stable than glycine under the conditions studied.—H. G. Bray.

165
TATARENKO, E. S., SOBOL', A. E. and NOVIKOVA, Z. N. Izyskaniya antiokislitelei biologicheskogo proiskhozhdeniya dlya predokhraneniya

zhirov ot progorkaniya. [**Anti-oxidants of biological origin for the preservation of fats from rancidity.**] *Mikrobiologiya*, 1955, **24,** 217–222. [Ukraine Sci. Res. Inst. Food Indust., Kharkov.]

The object of this investigation was (1) to find moulds capable of accumulating fat in their mycelia, (2) to discover the optimum conditions for the formation of unsaponifiable matter, (3) to test the anti-oxidant qualities of unsaponifiable matter.

The mould *Naumoviella oleaginosa Tatarenko* sp. nov. was chosen for the test. Other moulds investigated were *N. humicola* and *Mortierella* sp. 2. All were shown to have a great capacity for fat accumulation. The last 2 were not tested for anti-oxidant properties. The optimum temperature for the development of *N. oleaginosa* was from 25° to 26° C. A lower temperature slowed down the growth of the culture but did not affect the accumulation of fat. The optimum *p*H of the nutrient medium (potato-glucose) for fat accumulation was from 4·8 to 5. The addition of from 0·2 to 1 per cent. KH_2PO_4 increased the capacity of the mould for fat accumulation, which was high, between 45 and 52 per cent. of the dry weight of the mould film. With beer wort as a medium the amount was from 20 to 52 per cent. The accumulation of unsaponifiable matter when the moulds were grown under identical conditions varied considerably, 1 per cent. unsaponifiable matter being obtained in one experiment, 16·2 per cent. in another. The unsaponifiable part of the lipids of *N. oleaginosa* contains substances with anti-oxidant properties, which at a concentration of 0·01 per cent. increase the stability of food fats 3·5 times. The unsaponifiable matter amounts to from 1 to 18 per cent. of the weight of the lipids.

A sample of butter used as a control became rancid within 28 days ; a sample with unsaponifiable matter from *N. oleaginosa* began to be rancid only after 86 days.—H. Scherbatoff.

Köttgen, U., Braun, E. and Friedberg, V. Gefriertrocknung zur Konservierung von Frauenmilch. [**Freeze-drying for preservation of human milk.**] *Deutsch. med. Wochenschr.*, 1955, **80,** 923–925. [Kinderklin., Univ. Mainz.]

Tests were made with human milk freeze-dried by the process of Catel *et al.* (Abst. 167, Vol. 24), which produces from 100 g. fresh milk 12·5 g. powder with a residual moisture content of 2 to 3 per cent. Paper electrophoresis of reconstituted freeze-dried milk gave results similar to those with fresh human milk ; boiled or pasteurised milk showed changes. Bacteriological tests showed no increase in harmful organisms during freeze-drying storage. Of 6 premature infants who were thriving on fresh human milk without supplement, 4 showed better average daily weight gains during 2 weeks when they had the dried milk instead ; their general condition and the appearance and bacterial flora of their stools were unaffected. Remaining obstacles to the wider use of the process are the high cost and the absence of a satisfactory method of reducing the number of bacteria in the raw milk, since the process does not kill them but merely prevents their multiplication.

ase in ripening sour milk cheese.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **102,** 13–27; 97–106. [Inst. Lebensmittelchem., Tech. Univ., Berlin Charlottenburg.]

For previous parts see Absts. 4263, Vol. 24; 220, 1774, 3259, Vol. 25.

13. The following are some of the findings of this detailed study of glutamic acid decarboxylase in ripening Harz cheese. The activity of the enzyme in a suspension of cheese 6 to 7 days old was much greater at 37° than at 30° C. The optimum *p*H lay between 4·8 and 5·2. Since addition of pyridoxal-5′-phosphate, the coenzyme, only slightly increased the activity, it was concluded that little surplus apoenzyme was present. During normal ripening, glutamic acid decarboxylase increased up to 10 days and then showed a decline, which was prevented by addition of the coenzyme. Activity was greater in the crust of the cheese than inside. γ-Aminobutyric acid, a frequent breakdown product from decarboxylation of glutamic acid, was detected in the cheese by paper chromatography.

In the discussion it is pointed out that vitamin B_6 in its phosphorylated form plays a double part in cheese ripening, as growth substance for bacteria and as coenzyme of the enzymes which the bacteria produce, and it is considered probable that the same is true of other vitamins.

14. Lysine decarboxylase was studied in the same materials as above. Its optimum *p*H lay between 5·1 and 5·8. Its activity was greatly increased by addition of pyridoxal-5′-phosphate. During normal ripening, lysine decarboxylase rose from the third to the sixth day and fell slowly after the tenth day; if pyridoxal phosphate was added, the rise was initially steeper and continued to the twentieth day, reaching a value over 7 times that without addition. Cadaverin, the product resulting from decarboxylation of lysine, was identified by paper chromatography in very ripe Harz cheese. Although milk is relatively low in vitamin B_6, so that curd is unlikely to contain much pyridoxal phosphate, any destruction of lysine implies irreparable damage to protein, and experiments on the fate of this amino-acid in ripening cheese are in progress.—W. M. Deans.

GERRITSMA, K. W. and FREDERIKS, J. C. Über die Hydrolyse kondensierter Phosphate während der Bereitung und Lagerung gekochter Wurst. [**Hydrolysis of condensed phosphates in the preparation and storage of cooked sausage.**] *Centraal Inst. Voedingsonderzoek T.N.O. Utrecht, Publ.* No. 196. Repr. from *Deutsche Lebensmittel-Rundschau*, 1955, **51,** 130–132.

Addition of condensed phosphates to sausages to improve appearance and consistency has been legal in the Netherlands since 1952. As Gosselin *et al.* (*J. Pharmacol. Exp. Therap.*, 1952, **106,** 180; 1953, **108,** 117) have since raised doubts about their safety, it was desired to find out how far these compounds are hydrolysed to the harmless orthophosphate during the preparation and storage of cooked sausage. Orthophosphate was estimated by the method of Weil-Malherbe and Green (*Biochem. J.*, 1951, **49,** 286) in sausage meat containing 0·5 per cent. of a 4 : 1 mixture of sodium phosphate and Kurrol's salt (octametaphosphate, a long-chain polyphosphate) and either smoked in skins and cooked for 1 hr. at 80° C., or canned and cooked for 3 hr. at 100° C. or 2 hr. at 112° C. The percentage of condensed phosphate hydrolysed was 31, 25 and 69, respectively, and in cooked smoked sausage hydrolysis continued during storage for up to 3 months. Another experiment showed that pyrophosphate is more readily hydrolysed than Kurrol's salt when heated with meat for 3 hr. at 100° C.—W. M. Deans.

SORGER-DOMENIGG, H., CUENDET, L. S., CHRISTENSEN, C. M. and GEDDES, W. F. **Grain storage studies. 17. Effect of mold growth during temporary exposure of wheat to high moisture contents upon the development of germ damage and other indices of deterioration during subsequent storage.** *Cereal Chem.*, 1955, **32**, 270–285. [Dept. Agric. Biochem., Inst. Agric., Univ. Minnesota, St. Paul.]

Half of a 40 kg. sample of sound hard red spring wheat of low mould count was inoculated with moulds (*Aspergillus* and *Penicillium* spp.) and the other half was treated with sodium hypochlorite before samples were kept for 5, 10 or 15 days at moisture contents of 15, 18 or 21 per cent. and subsequently stored in sealed jars at 14 per cent. moisture for 2 to 12 months before examination and small-scale milling and baking tests. Wheat with 21 per cent. moisture was also stored at 13 per cent. moisture.

Mouldiness greatly increased the germ damage, loss of viability and increase in fat acidity which resulted from temporary storage at a high moisture content, and although mould counts fell during subsequent storage at 14 or 13 per cent. moisture, germ damage and fat acidity went on increasing. Mouldy wheat held at 21 per cent. moisture had poor milling and baking qualities and the baking quality continued to deteriorate during storage at 14 per cent. moisture.

It is suggested that evaluation of wheat quality and prediction of its storage behaviour may require a combination of criteria, namely, moisture content, mould count, viability and fat acidity.

KIERMEIER, F. and CODURO, E. Über den diastatischen Stärkeabbau in lufttrockenen Substanzen. [**Diastatic breakdown of starch in air-dried substances.**] *Biochem. Ztschr.*, 1954, **325**, 280–287. [Deutsch. Forschungsanst. Lebensmittelchem., Munich.]

The rate of breakdown of soluble starch by diastase at 37° C. increased with the water content when this was between 14 and 42 per cent.; above that it was constant. In presence of plant fibres (filter paper, supporting fibres of beech leaves) the enzyme was active down to 5·5 per cent. moisture, corresponding to a relative humidity of 46 per cent. in the air.—W. M. Deans.

[Deutsch. Forschungsanst. Lebensmittelchem., Munich.]

For previous parts see Title 3149, Vol. 24 and preceding Abst.

3. This is part of a thesis by Coduro (Univ. Munich, 1953). At 30° C. the natural amylases, and also the proteases, of rye flour behaved like diastase (see preceding Abst.) except that there was no sharp change at a definite moisture content. Breads already shown (Abst. 283, Vol. 24) to retain amylase activity after baking were stored at 30° C. In "Knäckebrot" breakdown of starch was demonstrated even when the moisture content was as low as 5·14 per cent., corresponding to a relative humidity of 36 per cent.; this is ascribed to its porous structure. Breakdown of starch also occurred in wheat rolls and "Schlüter" (fine wholemeal) bread and rolls. It is thought likely that proteolytic breakdown may occur also during storage of bread and other dry foods.

HISZPAŃSKA, C., PŁOŃSKA, H., RUTCZYŃSKA-SKONIECZNA, E., SZACHOWSKA, M. and ZALĘSKI, J. Wpływ dodatków innych arykułów żywności na wartość higieniczną chleba. [**The effect of some supplementary food products on the nutritive and organoleptic value of bread.**] *Rocz. Państwowego Zakł. Hig.*, 1955, **6**, 141–148. [Zakł. Badania Żywności i Przedmiotów Użytku PZH.] Russian and English summaries.

The addition of potato flakes or potato flake powder did not improve the nutritive value or taste of bread. Flakes of poor quality, containing large quantities of peel, increased the fibre content. The addition of whey, while improving the baking quality and the Ca content of the bread, greatly increased the acidity. Defatted soya bean flour increased the mineral content of sweet baked products but not the protein content, and introduced an undesirable flavour.—J. S. Thomson.

184

KIK, M. C. **Influence of processing on nutritive value of milled rice.** *J. Agric. Food Chem.*, 1955, **3**, 600–603. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.]

The systems of processing to which the rice had been subjected were the rice conversion process in which it is soaked and dried *in vacuo* and the Malek process in which rice is steamed under pressure. Analytical data are presented for proximate constituents and for contents of vitamin B complex components, Ca, P and Fe and 17 amino-acids ; biological value and digestibility for the rat are given. The general improvement in nutritive value produced by such treatments is confirmed.

[**Use of sprout-inhibiting substances in storing ware potatoes. 3. Experiments in the storage seasons 1952-53 and 1953-54.**] *Kungl. Lantbruksakad. Tidskr.*, 1955, **94**, 141–158. English summary.

For previous parts see Absts. 4542, Vol. 19 ; 190, Vol. 22.

Sprouting of potatoes was satisfactorily inhibited by spraying the crop with maleic hydrazide, 2500 g. per hectare, from 4 to 6 weeks before lifting. Treated potatoes did not blacken so readily on boiling. Nevertheless, the practice is not generally recommended, since weight loss on storage was increased and, with some varieties, loss due to disease was also increased.

Additional studies with other chemicals showed that a preparation of dinitrotoluene was slightly and one of *iso*propylphenylcarbamate ten times more powerful than Fusarex (tetrachloronitrobenzene).—W. M. Deans.

KIERMEIER, F. and RICKERL, E. Über die Ursachen der Verfärbung gedämpfter Kartoffeln. 1. Der Einfluss phenolischer Körper. [**Causes of discolouration of steamed potatoes. 1. Effect of phenolic substances.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **100**, 441–449. [Deutsch. Forschungsanst. Lebensmittelchem., Munich.]

The literature is reviewed with special reference to phenolic substances as a possible cause of discolouration of cooked potatoes.

Paper chromatography of alcoholic extracts with a 4 : 1 : 5 mixture of butanol, acetic acid and water as solvent and ferrous sulphate or phosphomolybdic acid as developer revealed the presence in steamed peeled old potatoes of a single variety, per 100 g. fresh substance, of from 24 to 37 mg. chlorogenic acid (simultaneously discovered as a constituent of potatoes by Johnson and Schaal (*Science*, 1952, **115**, 627)). New potatoes had about half and old raw peeled potatoes about a tenth as much. Small amounts of caffeic acid were detected also. Chlorogenic acid gives a greyish green colour with salts of Fe and is considered a possible cause of discolouration of potatoes.—W. M. Deans.

189

SCHOUSTRA, A. and WILLEMS, J. J. L. Het koken van aardappelen voor het zoutlose dieet. [**Boiling potatoes for the salt-free diet.**] *Voeding*, 1955, **16**, 706–708. [Centraal Inst. Voedingsonderzoek T.N.O., Utrecht.] English summary.

The question whether unpeeled potatoes boiled in salted water along with peeled potatoes remain sufficiently free of salt to be harmless to patients on a salt-free diet is discussed. Three experiments were made : (1) unpeeled potatoes were boiled along with peeled potatoes in water containing 1 g. salt per 100 g. peeled potatoes ; the water half-covered the potatoes and had to be poured off after boiling ; (2) the unpeeled potatoes were placed on a saucer on top of the peeled ones, otherwise the conditions were as above ; (3) as (2), but no salt was added to the water. Raw peeled potatoes were found to contain 20 mg. salt per 100 g. potato, peeled potatoes boiled in salted water 356 mg. and unpeeled 18 mg. If the unpeeled potatoes were put on a saucer they contained 13 mg. per 100 g. in the pan with salted water and 8 mg. in

the pan without salt. It is therefore permissible to boil potatoes in salted water for patients on a salt-free diet, provided the potato skins are unbroken.—M. Eddison.

LEE, F. A., WAGENKNECHT, A. C. and HENING, J. C. **A chemical study of the progressive development of off-flavor in frozen raw vegetables.** *Food Res.*, 1955, **20,** 289–297. [New York State Agric. Exp. Stat., Cornell Univ., Geneva.]

In continuation of previous work (Title 1483, Vol. 21 ; Abst. 1734, Vol. 25), unblanched peas, snap beans and sweet corn frozen and stored at 0° F. for up to 2 years were found to develop off-flavours after about 2 weeks ; some persons could not detect these even much later, which possibly accounts for statements that blanching is not essential. Crude lipids extracted from the vegetables began to increase in acidity after about 1 week. Peroxides did not appear till later, after 3, 4 and 8 weeks, respectively. As was found earlier, peroxides appeared in the lipids of blanched sweet corn after 18 months.—W. M. Deans.

MOORJANI, M. N. and BHATIA, D. S. **Storage effects on the proteins of groundnuts.** *J. Sci. Indust. Res.* [*B*], *India*, 1954, **13,** 113–114. [Central Food Technol. Res. Inst., Mysore.]

Groundnuts stored for 18 months at 20° to 30° C. showed a loss of true protein N of 11 per cent., of N soluble in NaCl of 10 per cent. and of N in the NaCl extract precipitable by trichloroacetic acid of 14·6 per cent. Digestibility estimated by pepsin and trypsin digestion was reduced by 7·9 per cent. The protein had become partly denatured.

J. S. Thomson.

NOWAK, E. Qualitätsprüfung von Sojakuchen und -Extraktionsschroten. [**Testing the quality of soya cakes and extracted meals.**] *Bodenkultur*, 1954, **8,** 54–56. [Landwirtsch. Chem. Bundesversuchsanst., Vienna.]

In 3 dark-coloured samples of soya meal 2 or 3 times as much of the crude protein was non-digestible as in a normal sample, which pointed to damage of the proteins by overheating. In only one of them did the proportion of free fatty acids, as oleic acid, in the oil exceed 50 per cent., the figure suggested as a normal limiting value. Soya cake should not have more than 15 per cent. of free fatty acids in the oil.—W. M. Deans.

GRAU, C. R. and ZWEIGART, P. A. **The effects of various processing methods on the value of cottonseed meal as an amino acid source for chickens.** *Poultry Sci.*, 1955, **34,** 724–728. [Dept. Poultry Husb., Davis, Calif.]

Cottonseed meals, free from gossypol, produced in 24 different ways, were compared in trials with chicks from hatching to 2 weeks of age. The methods of production included screw and hydraulic press and solvent extraction at temperatures from 188° to 240° F. Some of the meals were commercial products about which information on the temperature was not available, and others were prepared in the laboratory. The percentage of protein in the meals ranged from 34 to 58, and in the trial each was included in a standard ration to give a total of 20 per cent. protein. As a control a similar ration with fishmeal was used. The results, based on comparison of growth rates, showed that some of the meals were satisfactory, but there was no guarantee that any one method would produce a satisfactory meal. There was some indication that the better meals were produced at the lower temperatures.—T. D. Bell.

196

DIJKSTRA, N. D. Proefnemingen over het bewaren van natte bostel. [**Experiments on the preservation of brewer's wet grains.**] *Versl. Landbouwk. Onderzoek.*, 1955, No. 61.4, pp. 11. English summary.

Two lots of brewer's grains each of roughly 10,000 kg. were ensiled, one in a waterproof concrete silo and one in a pit. Analyses before and after storage from April to December and the results of 10-day digestibility trials with wethers in which the grain was given with 300 g. dried clover are reported. Mean digestibility coefficients for silo and pit silage were : organic matter 64·9 and 55·0, crude protein 78·3 and 70·6, crude fat 91·8 and 90·2, N-free extract 57·9 and 44·3, crude fibre 51·0 and 38·3. The silo silage was of better quality, with less butyric acid, and percentage losses were less, 12·2 as against 29·8 for digestible crude protein and 13·7 as against 31·0 for starch equivalent.—I. Leitch.

197

DIJKSTRA, N. D. and SPRENGER, J. J. I. Proefnemingen over de achteruitgang van de verteerbaarheid bij het kunstmatig drogen van gras. [**The effect of artificial drying on the digestibility of grass.**] *Versl. Landbouwk. Onderzoek.*, 1955, No. 61.1, pp. 24. English summary.

Improvements have recently been made in the technique of drying grass. In high-temperature driers inlet and outlet temperatures are from 600° to 900° and from 140° to 180° C. In low-temperature band driers inlet and outlet temperatures are below 200° and from 120° to 140° C. Experiments with different samples of grass chopped, dried at high temperatures and sometimes ground and cubed, or dried at low temperatures, showed little difference in digestibility by wethers. Protein was most affected, but even so the reduction was only 2 to 3 per cent. or 5 to 6 per cent. after grinding and cubing. Carotene also was lost in grinding and pressing. In high-temperature drying the inlet temperature does not appear to matter. A low outlet temperature determines quality.

I. Leitch.

198

DIJKSTRA, N. D. and BRANDSMA, S. Proefnemingen over het ensileren van voorgedroogd gras. [**Experiments on silage making by the wilting method.**] *Versl. Landbouwk. Onderzoek.*, 1955, No. 61.3, pp. 45. English summary.

A detailed account is given of 3 years' silage making with wilted grass: 1951, spring and autumn silage, 1952, one spring and two autumn, 1953, three spring silages, and in 1952 and 1953 hay made on frames from the same grass. Butyric acid in silage varied inversely with the dry matter content. Losses of digestible crude protein ranged from 16·1 to 33·4, average 24·2 per cent., and of starch equivalent from 20·8 to 36·3, average 27·5 per cent. The losses in silage of digestible crude protein in the 2 years were about 71 and 58 per cent. and of starch equivalent 66 and 62 per cent. of the losses in hay from the same crop.

I. Leitch.

199

PARISH, D. H. **The losses on conservation with mineral acid silage produced in small silos.** *Res. and Exp. Rec. Minist. Agric. N. Ireland*, 1952–53 (1955), **3**, 160–165.

A small-scale experiment with Italian ryegrass ensiled with a 2 : 1 mixture of HCl and H_2SO_4 under pressure in 4 dustbins with holes in the base for drainage is reported, with tables of analytical findings. After 11 months the silage was of excellent quality, with *p*H from 3·93 to 4·03. Loss of organic matter was high, about 30 per cent.; this was not due to moulding but may have been due to the presence of yeasts. There was, however, no loss of crude protein, which shows the possibilities of the A.I.V. method for preserving herbage rich in protein.—W. M. Deans.

200

ALDERMAN, G., COWAN, R. L., BRATZLER, J. W. and SWIFT, R. W. **Some chemical characteristics of grass and legume silage made with sodium metabisulfite.** *J. Dairy Sci.*, 1955, **38**, 805–810. [Dept. Animal Nutrit., Pennsylvania State Univ., University Park.]

Forty-eight samples of silage made from grass and legumes, either mixed or separately, with the addition of 8 to 10 lb. sodium metabisulphite per ton of green matter were analysed. The average *p*H was 4·49, a value higher than is found in good silage made by other methods. Lactic acid values were low also, but the silage was nevertheless well preserved, little butyric acid was formed and protein breakdown was satisfactorily reduced. It is suggested that in silage made by this method it is the action of the bisulphite ion, not the hydrogen ion, that is important.—T. D. Bell.

201

BRATZLER, J. W., COWAN, R. L. and SWIFT, R. W. **Preservation of grass silage with sodium metabisulfite.** *Pennsylvania Agric. Exp. Stat. Bull.* No. 597–P, April 1955, pp. 6.

Grass silage can be preserved for long periods by the addition of 8 lb. bisulphite per ton of forage in a tower silo or 10 lb. per ton in a trench silo. (See Abst. 3322, Vol. 25.)—J. S. Thomson.

202

FOOT, A. F., MURDOCH, J. C. and ROWLAND, S. J. **Marrowstem kale silage.** *Empire J. Exp. Agric.*, 1955, **23**, 109–112. [Nat. Inst. Res. Dairying, Reading.]

Kale was ensiled in large and small silos. The dry matter of the kale before ensiling ranged from 14·6 to 15·4 per cent. and the crude protein from 11·3 to 14·8 per cent. of the dry matter; after ensiling, from 16·45 to 18·13 and from 12·0 to 14·4 per cent., respectively. Loss of dry matter was highest in the large silos, 32·5 to 37·8 per cent. as against from 23·9 to 25·1 in the small silos, but in the latter the loss of dry matter in the effluent was much higher. The addition of chopped hay before ensiling had no beneficial effect on the quality of the silage or on the amount of seepage.

WILLIAMS, H. H. **"Essential" amino acid content of animal feeds.** *Cornell Univ. Agric. Exp. Stat. Memoir* No. 337, January 1955, pp. 31.

Microbiological methods are discussed and the procedure is fully described for estimating arginine, *iso*leucine, threonine, tryptophan, tyrosine and valine with *Streptococcus faecalis*, and histidine, leucine, lysine, methionine and phenylalanine with *Leuconostoc mesenteroides*. Data for the content of N and of these 11 amino-acids are presented for 69 feedingstuffs commonly used as sources of protein for animals, and their applicability in the calculation of the amino-acid content of mixed feeds is demonstrated.—D. Harvey.

204

BONDI, A. and BIRK, Y. **The action of proteolytic enzymes on protein feeds. 1. Liberation of terminal groups from peptic and pancreatic digests.**

BIRK, Y. and BONDI, A. **2. Intermediary products precipitated by trichloroacetic acid and phosphotungstic acid from peptic and pancreatic digests.** *J. Sci. Food Agric.*, 1955, **6**, 543–548; 549–556. [Agric. Res. Stat., Rehovoth, Israel.]

1. The liberation of terminal groups (COOH, NH_2 and α-NH_2) and the COOH : NH_2 ratio in digests of typical animal and plant protein feeds *in vitro* by pepsin and pancreatin was characteristic of the enzyme and independent of the substrate. Plant proteins were more soluble than animal proteins. Digestion with pepsin released small amounts of α-NH_2 groups, pancreatin more and pancreatin digestion after incubation with pepsin still more.

2. The feeds of the previous experiment were enzymically digested and treated with trichloroacetic and phosphotungstic acids. The number of amino-acids in the peptides precipitated by trichloroacetic acid from a pancreatin digest of plant proteins ranged from about 20 to 30. This relatively stable protein fraction was not found in animal feeds. Its presence in plant feeds is suggested as a possible reason for the lower nutritive value of plant proteins.—A. Hepburn.

FOODSTUFFS OF ANIMAL ORIGIN

Milk and Milk Products

205

FORD, T. F., RAMSDELL, G. A. and LANDSMAN, S. G. **Composition of the casein-containing particles in milk.** *J. Dairy Sci.*, 1955, **38**, 843–857. [E. Utilization Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Washington 25, D.C.]

Most casein in particles from fresh skimmed milk appeared to be a single phosphoprotein, which from the organic P : N ratio was probably a mixture of α-, β-, and γ-caseins or, alternatively, the latter existed separately in particles of comparable size. Calcium and $Ca_3(PO_4)_2$ were considered to be combined with phosphoprotein as a complex. Inorganic P varied between milks and decreased with particle size, but in milks of low Ca content and for the smallest particles removed there was a definite minimum proportion. The largest particles had a different composition and contained some non-protein material.

RIEL, R. R. **Variation in fat constants of genuine Canadian milk fat.** *J. Assoc. Off. Agric. Chem.*, 1955, **38,** 494–503. [Sci. Serv., Canada Dept. Agric., Ottawa.]

Reichert Meissl and Polenske values and refractive index are tabulated for monthly samples from June 1953 to May 1954 from 29 butter factories representative of dairying regions in the 8 provinces of Canada, with graphs of frequency distributions. The monthly averages for all factories represent about 5300 herds and 39,000 cows. The overall averages and 95 per cent. fiducial limits were: Reichert Meissl value 27·8, 25·1 to 30·5; Polenske value 2·0, 1·4 to 2·6; refractive index 1·45419, 1·45326 to 1·45512. The ranges are narrower than those reported in the literature. Differences between provinces and between months were significant. Reichert Meissl values decreased from June to November and rose from November to April. The decline in autumn may be due to poor feeding and bad weather or to end of lactation. Polenske values were highest in June and July and refractive index was high in summer and low in winter.—W. M. Deans.

SCHÄFER, K. H., BREYER, A. M. and KARTE, H. Das Spurenelement Eisen in Milch und Milchmischungen. **[The trace element iron in milk and milk mixtures.]** *Ztschr. Kinderheilk.*, 1955, **76,** 501–513. [Kinderklin., Univ. Göttingen.]

Since the published values for the Fe content of human and cow's milk, found by ashing, vary widely, an extensive study was made in which Fe soluble in 6*N* HCl was estimated colorimetrically by the phenanthroline method as used by Heilmeyer and Plötner (*Das Serumeisen und die Eisenmangelkrankheit*, Jena, 1937) in several hundred samples of human milk at different stages of lactation; and from 50 to 70 analyses were made of cow's, ewe's and goat's milk and of cereal gruels and other preparations for feeding infants. Some of the results have appeared already (Title 2355, Vol. 20; Abst. 191, Vol. 21; Schäfer, *Erg. inn. Med.*, 1953, **4,** 705).

Human milk is richer in Fe than the milks of the animals studied, but the amount declines from over 120 μg. per cent. in the first 10 days to about 90 after 6 months. These are 1947–48 values, but those of Klarczyk (*Thesis*, Univ. Hamburg, 1954), in 1953–54 when food supplies were normal, are similar. The decline seems to be less in summer than in winter. Contrary to the view of Albers (*Eisen bei Mutter und Kind*, Leipzig, 1941), giving Fe by mouth to the nursing mother does not raise the Fe content of her milk.

For the milk of cow, ewe and goat collected in aluminium or glass vessels in summer the respective values 67, 64 and 25 μg. per cent. were found. Of the cereal gruels, 5 per cent. oatmeal gruel had most, 294 μg. per cent.; gruel of barley 173, of dried barley 266 and of rice only 86 μg. The usual "half-milk" prepared with 5 per cent. oatmeal gruel and 5 per cent. sugar had 188 μg. It is suggested that the greater liability to anaemia of infants fed on mixtures of cow's milk and oatmeal than of breast-fed infants may be due to interference with Fe absorption by the phosphates of cow's milk and the phytic acid of oatmeal. Soya milk is remarkably rich in Fe (1000 μg. per cent.) and this Fe is available, as has been shown by Borngräber (*Thesis*, Univ. Göttingen, 1951) with anaemic infants, and by Krause (*Thesis*, Univ. Göttingen, 1951) with rats anaemic from feeding on cow's milk.

The Fe in milk is not dialysable. The percentage of the total Fe (found by ashing) soluble in 6*N* HCl was 72 for human milk, 79, 91 and 86 for the milk of cow, ewe and goat, respectively, and 97 for soya milk. That is, the acid-soluble Fe can be taken as representative of the total Fe.

Studies of the distribution of acid-soluble Fe in human and cow's milk showed that only about half is in the skimmed milk or whey and most of the other half is bound to fat. Electrophoretic studies of whey, both human and cow, to be more fully reported elsewhere, showed that most of the Fe is associated with the immune globulins, not with β-lactoglobulin. This has been confirmed with milk to which radio-active Fe was added (Title 1950, Vol. 24) and by preliminary experiments with the ultracentrifuge.—W. M. Deans.

MANI, G. S., LILY, G., BALASUBRAMANIAN, S. C. and BASU, K. P. **Composition and nutritive value of some indigenous milk products.** *Indian J. Med. Res.*, 1955, **43,** 237–242. [Dairy Chem. Sect., Indian Dairy Res. Inst., Bangalore.]

Samples of boiled milk, dahi (curd), khoa, kheer and channa, the forms in which milk is commonly consumed in India, were analysed for fat, protein,

lactose, minerals, total solids, Ca, P, vitamin A, vitamin B_1, riboflavin, nicotinic acid and ascorbic acid. The samples of milk and of the products were all from a mixed lot of fresh cow's milk.

Milk had a higher nutrient content than any of the products. Dahi had slightly lower vitamin A, vitamin B_1, riboflavin and nicotinic acid contents than milk; the lactose content of milk decreased by about 34 per cent. on curdling. Khoa had lower vitamin A and C contents; kheer had a composition similar to that of milk but had less vitamin A and C. Channa had the lowest content of nutrients, especially of vitamins of the B group, lactose, vitamin A and ascorbic acid; it had no nicotinic acid.—G. F. Garton.

(See also Absts. 881–3, Vol. 26).

NUÑEZ DE LOS RIOS, J. M. Análisis bromatológico y microbiológico de las cremas lácteas. [**Bromatological and microbiological analysis of cream.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 127–129.

Studies were made on 4 kinds of cream, 2 thin and 2 thick, obtainable commercially in Lima. The mean composition was water 56·13, fat 34·04, protein 2·24 and sugar 3·39 per cent. The mean vitamin A content was 146 I.U. [? per g.]. All the samples contained traces of gelatine. Bacterial counts were of the order of 41,000 per ml. or g.—D. Duncan.

216

BROGIONI, M. Recherche et dosage du diacétyle dans le beurre produit dans la province de Pérouse. [**Studies on and estimation of diacetyl in butter produced in the province of Perugia.**] *Lait*, 1955, **35**, 276–282. [Lab. Provinc. Igiene Profilassi, Reparto Chim., Perugia.]

Fifty g. butter was steam-distilled between 105° and 110° C. and the first 15 ml. of distillate was collected in 5 ml. distilled water. Diacetyl was estimated by the method of Pien (Title 4373, Vol. 19). Values found in different butters ranged from 0·46 to 0·80 mg. per kg.

WEGELIN, E. **On the proteins of milk whey. The nitrogen distribution in whey, electrophoretic characterization of proteins, and feeding experiments.** *Versl. Landbouwk. Onderzoek.*, 1952, No. 58·3, pp. 147.

For preliminary reports on this work see Seekles and Wegelin (Abst. 1043, Vol. 23), Seekles (Vergadering van het Genootskap ter bevordering van Melkkunde, Utrecht, 1951, *Nederlands Melk Zuiveltijdschr.*, 1951, **5**, 259 and Wegelin, *ibid.*, 263.

In the Netherlands about 1 million tons of whey are produced annually. Of this about 2 per cent. is used as food, some for animal feed and the rest is wasted. A certain amount of lactalbumin for animal feeding is got as a by-product of the lactose industry, but it is injured by heat denaturation.

This report describes studies by electrophoresis of proteins in whey as delivered from cheesemaking, *i.e.*, from pasteurised milk, and after further heat treatment, salting out, electrodialysis and condensing. Dried whey also was analysed. There are 4 main components: (1) "Whey protein", which occurs in rennin whey but not in acid whey, (2) β-lactoglobulin, (3) a highly soluble albumin not yet identified, and (4) a heterogeneous globulin fraction (that precipitated by saturation with $MgSO_4$) with which the immune bodies of milk are associated.

Ultracentrifugal analysis gives 3 components of which the first, the α-fraction, includes (1) and (3) of the electrophoretic analysis.

In terms of decreasing resistance to heat, fraction $3 > 2 > 1 > 4$. Condensing at temperatures below 49° C. has little effect beyond that already produced by pasteurisation. Electrolytic desalting removes part of the N.P.N. of whey and causes further slight changes in the residue. Analysis of samples of dried whey showed that the electrolytic process removes riboflavin with lactose and vitamin B_{12} possibly directly.

To compare whey proteins from cow's milk with those from breast milk, the breast milk was centrifuged to remove fat and the casein was coagulated with $CaCl_2$, citric acid and rennet. The clear filtrate was dialysed against a citrate-phosphate-KCl buffer and concentrated by freezing to a protein concentration of 1·04 g. per 100 ml. Component (1) of cow's milk whey was absent; the first component of breast milk whey corresponded

to β-lactalbumin but was present in a concentration of only 10 per cent. as compared with 54 per cent. in cow's milk whey. The main components were two more slowly moving proteins for which the ascending and descending patterns were so different that, with the amount of milk available, further analysis was not possible. They were different from the bovine constituents.

A further study of pooled breast milk, from the Milk Bank, pasteurised and lyophilised, again showed no "whey protein", β-lactoglobulin, a component corresponding to (3) in cow's milk whey and a third corresponding to the third component in fresh breast milk but of different mobility.

In experiments in which rats, chicks, twin calves and pigs were given whey, dried or desalted and dried, the lactose was inefficiently used (as shown by reducing substances in faeces and urine). The proteins were considered to be of as high value as other animal proteins.—I. Leitch.

Eggs

218

TSUJI, F. I., BRIN, M. and WILLIAMS, H. H. **Lipide phosphorus and cholesterol changes in the hen's egg during incubation.** *Arch. Biochem. Biophys.*, 1955, **56,** 290–296. [Dept. Biochem., Cornell Univ., Ithaca, N.Y.]

Eggs from White Leghorn hens were incubated at 37·8° C. for from 6 to 21 days. The eggs were then dissected into embryo and residual yolk and each portion was analysed for lipids.

Lecithin P, cephalin P, total lipid choline and free cholesterol decreased, with incubation, in the residual yolk and showed a corresponding increase in the developing embryo; a progressive increase in esterified cholesterol occurred in both embryo and yolk. Although the unincubated egg contained almost no sphingomyelin, some was synthesised in the developing embryo. The total cholesterol content of the whole egg did not change appreciably during incubation.—G. A. Garton.

Meat (All Kinds)

220

REITH, J. F., HOFSTEEDE, M. J. N. and LANGBROEK, W. **The nitrogen content of meat and the calculation of the meat content of meat products.** *J. Sci. Food Agric.*, 1955, **6,** 317–323. [Dept. Food Chem., Univ. Utrecht, Catharijnesingel 60.]

The formula of Stubbs and More for the calculation of "lean meat content" of meat products on the basis of their N content is discussed, in particular, the factors 3·4 for beef and 3·6 for pork. Published analyses of English, Dutch, American and German meat permitted calculation of the mean N content of fat-free beef and pork; for pork the factor 3·6 of the Stubbs and More formula was found to be higher than most of the values thus obtained. The relation between the Stubbs and More factors and the district where the animal was reared, the age of the animal and the fat content of the meat is discussed. N, fat and moisture were estimated in 19 samples of fresh Dutch pork and 19 samples of salted Dutch pork. The mean Stubbs and More factor for the fresh pork was found to be 3·4. The mean factor obtained for animals aged from 5½ to 6 months was the same as that for animals aged from 7 to 8 months. The data showed a slight negative correlation between the fat content and the Stubbs and More factor, but more significant was the influence of breed, as Yorkshire pigs generally showed a lower Stubbs and More factor than the "Veredeld Landvarken" stock. The losses of moisture and protein during the salting of the pork are calculated.—G. F. Garton.

Fish

224

CASTRO G., G. L. Análisis químico bromatológico de carnes y ovas ahumadas de la Serda

Chiliensis, " Bonito ". [**Bromatological chemical analysis of smoked flesh and roe of *Serda chiliensis*, bonito.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 66–74. [Lab. Tecnol., Pesquera, Callao.]

Salted and smoked flesh and roe of bonito contained, respectively, dry matter 45·3, 72·3, protein 35·9, 34·0 and ether extract 6·4, 10·9 per cent. The fat of the flesh contained 7420 I.U. vitamin A and 724 I.U. vitamin D per g. The flesh supplied 290·9 and the roe 233·5 Cal. per 100 g. The protein content was about 10 per cent. higher than that of fresh fish. When smoked at 80° to 85° F. for 25 hr. the preserved material kept well for 3 months.—T. D. Bell.

225

CISNEROS A., V. Preparación y estudio bromatológico de la carne ahumada del Mustelus Dorsalis o " tollo blanco ". [**Preparation and bromatological study of smoked flesh of *Mustelus dorsalis* (dogfish).**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 75–80.

The process of salting and smoking by the slow method of the flesh of the dogfish *Mustelus dorsalis* (" tollo blanco ") is described. The preserved flesh had dry matter 73·2, protein 52·2, ash 18·7 and ether extract 1·8 per cent. It supplied 225 Cal. per 100 g. and the fat contained 5500 I.U. vitamin A and 55 I.U. vitamin D per g.

T. D.Bell.

226

CÓRDOVA URTEAGA, A. Estudio bromatológico de la carne de Cheilodactylus Variegatus o " Pintadilla ". [**Bromatological study of the flesh of *Cheilodactylus variegatus* or " pintadilla " (the " painted fish ").**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 81–84.

Analysis of the flesh of the " painted fish " or " pintadilla " (*Cheilodactylus variegatus*) gave the following results : dry matter 24·5, protein 19·2 and ether extract 2·8 per cent. The fat had 8000 I.U. vitamin A per g., and 100 g. fresh material supplied 96·3 Cal. The fish had a pleasant taste and could be recommended for human consumption.

T. D. Bell.

227

GALLEGOS VILLA, A. Contribución al estudio bromatológico de la carne ahumada del Ethmidium Chilcae o " Machete ". [**Bromatological study of the smoked flesh of the spiny fish *Ethmidium chilcae* or " machete ".**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 103–108.

The spiny fish " machete " (*Ethmidium chilcae*) salted and smoked slowly for 4 days could be kept for 4 or 5 months. It had the following composition : dry matter 84·6, protein 52·9, ether extract 20·2 per cent. Vitamin A content was 11,332 I.U. per g. fat. It compared favourably with other fish of the Peruvian coast.—T. D. Bell.

228

MOCK MORALES, E. Contribución al estudio bromatológico de la Sciaena deliciosus (Lorna). [**Bromatological study of *Sciaena deliciosa* (a shore fish).**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 118–122.

The fresh and dried salted shore fish " lorna " (*Sciaena deliciosa*) contained, respectively, dry matter 25·5, 71·6 ; protein 16·0, 42·6 ; ether extract 2·0, 5·2 ; ash 1·5, 18·6 per cent. The energy values were 82 and 218 Cal. per 100 g. The fat of the fresh fish contained 6300 I.U. vitamin A. The salted product showed no sign of deterioration after 45 days.—T. D. Bell.

229

MORALES GALLEGOS, L. Estudio bromatológico de la carne ahumada del " Solea Vulgaris " o Lenguado. [**Bromatological study of the smoked flesh of *Solea vulgaris*, the sole.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 123–126.

Sole was preserved by salting and slow smoking. The smoked product, which could be kept for 4 or 5 months, had the following composition : dry matter 78·4, protein 51·8, ether extract 8·3, ash 17·4 per cent. The energy value was 282·5 Cal. per 100 g.—T. D. Bell.

230

PALOMINO G., J. A. Contribución al estudio bromatológico de la Sciaena Starksi—Robalo—. [**Bromatological study of *Sciaena starksi* (a shore fish).**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 148–155.

The flesh of the shore fish " robalo " (*Sciaena starksi*) contained, per cent. on fresh basis, protein 18·84, fat 2·82, carbohydrate 0·05 and ash 0·92. There was a high tyrosine content, 0·69 per cent., and a low tryptophan content, 0·20 per cent. The fat contained 12,008 I.U. vitamin A per g. The energy value was high. The fish can be successfully salted.—D. Duncan.

231

URCO NAJERA, A. Contribución al estudio bromatológico y ensayo de conservación de la Paralabrax Humeralis—cabrilla—. [**Bromatological study and attempt at preservation of *Paralabrax humeralis*, sea-bass.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 156–161.

The flesh of the sea-bass (*Paralabrax humeralis*) contained, per cent. on fresh basis, protein 16·77, fat 1·44, ash 1·10 and traces of carbohydrate. The percentages of tyrosine and tryptophan were 0·46 and 0·07. The fat contained 6930 I.U. vitamin A

per g. The energy value was 80 Cal. per cent., below the normal for fish.

The flesh was successfully salted and this could be done commercially. The salted fish contained, per cent., moisture 46·60, fat 2·77, ash 14·91, protein 34·91 and traces of carbohydrate. The energy value was again low for a dry product.

D. Duncan.

232

ZAMBRANO REYES, A. Análisis bromatológico de la carne de la "Merluccius Gayi" o Merluza seca (Peje Palo). [**Bromatological analysis of the flesh of *Merluccius gayi* (silver hake).**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 178–182.

Only small quantities of silver hake (*Merluccius gayi*) are caught off Peru. The analysis was made on the air-dried commercial product. The flesh contained 84 per cent. protein with 2·7 per cent. tyrosine and 1·25 per cent. tryptophan. The fat contained 9400 I.U. vitamin A per g.—D. Duncan.

233

CHEFTEL, R. I., MORETTI, J. and POLONOVSKI, J. Composition de l'huile de *Clupea pilchardus* Wal. en acides gras non saturés. [**Unsaturated fatty acid composition of the oil of *Clupea pilchardus*, Wal. (sardine).**] *Bull. Soc. Chim. biol.*, 1955, **37**, 709–714. [Lab. Biochem., Fac. Méd., Paris.]

Sardine (*Clupea pilchardus*) oil, 5 to 10 mg., was isomerised in a solution of ethylene glycol in KOH and diluted with methanol and the optical density was measured at 5 different wavelengths. From this the unsaturated fatty acid composition was calculated to within 5 per cent. error. The exact nature of each acid was not obtained, but it is suggested that hydrogenation followed by chromatographic analysis would give the proportion of acids as a function of their chain length. This information together with spectrometric data would allow a more precise estimation of the composition. The method was much better than other methods involving bromination and the use of lead and lithium salts.—A. Hepburn.

Other Types

234

CAIN, J. C. and MORTON, R. A. **Some minor constituents of liver oils.** *Biochem. J.*, 1955, **60**, 274–283. [Dept. Biochem., Univ. Liverpool.]

Liver lipids of Argentine shark, fin-whale, sheep, ox and horse were examined chromatographically, with particular reference to unsaponifiable matter. Ox liver fat unsaponifiable material yielded a compound $C_{19}H_{16}O$ [wrongly given as $C_{16}H_{19}O$ in summary], the absorption spectrum of which was indistinguishable from that of a compound isolated from butterfat by Morice (Abst. 1504, Vol. 21). Cholesta-3 : 5-dien-7-one, $\lambda_{max.}$ 270 mμ., was isolated from horse liver unsaponifiable material; another very similar substance, $\lambda_{max.}$ 272 mμ., probably containing 3 atoms of oxygen per molecule, was also obtained. In addition, horse liver lipids were found to contain a saturated higher aliphatic hydrocarbon and an unsaturated hydrocarbon, possibly hepene, $C_{45}H_{76}$. Carotenoids, mainly β-carotene, were found in horse, sheep and ox liver lipids. Horse kidney and spleen unsaponifiable matter contained, in addition to cholesterol, small amounts of 2 substances showing $\lambda_{max.}$ about 270 mμ. and 274 to 276 mμ., respectively, along with β-carotene and a waxy substance, probably a hydrocarbon.

G. A. Garton.

235

FERREYRA R., L. Estudio bromatológico de la carne del Lóligo Gahi "Jibia". [**Bromatological study of the flesh of *Loligo gahi* (a squid).**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 85–89.

The edible flesh of the squid "jibia" (*Loligo gahi*) had the following composition: dry matter 19·1, protein 15·7, ether extract 0·86. The energy value of 100 g. fresh material was 70·6 Cal. and the fat contained 6000 I.U. vitamin A per g.

T. D. Bell.

236

FLORES CASTAÑON, C. Valoración de los aminoácidos azufrados, metionina, cistina y cisteina en algunos moluscos. [**The sulphur amino-acids methionine, cystine and cysteine in some molluscs.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 90–98.

The methods are described in detail. The molluscs studied were species of squid (*Loligo*), mussel (*Mytilus*), "machas" (*Mesodesma*) and *Octopus*. The percentage of protein in dry matter was from 61 in *Mesodesma* to 88 in *Octopus*. On a dry matter basis, *Octopus* contained most methionine, 2 per cent., *Loligo* most cystine, 1·46 per cent., and *Mytilus* most cysteine, 0·54 per cent.

D. Duncan.

237

OKUYAMA B., V. Y. Contribución al estudio bromatologico [del] Thais Chocolata o "caracol negro". [**Bromatological study of *Thais chocolata* (an edible gastropod mollusc).**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 142–147.

The fresh flesh of the mollusc "caracol negro" (*Thais chocolata*) contained, per cent., protein 19·6, fat 0·6, carbohydrate 0·99 and ash 2·8. The ash contained, per 100 g., Ca 61·8 g., P 97, Fe 14 and Cu 2·2 mg. The vitamin A content was 6120 I.U. per g. fat. It is recommended that the mollusc be eaten fresh and not preserved.—D. Duncan.

238

VASQUEZ CASTILLO, A. Estudio bromatológico del Helix Aspersa " caracol común ". [**Bromatological study of *Helix aspersa*, the common snail.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 162–165.

The flesh of the snail, which is commonly eaten in Peru, contained on a dry basis protein 20, fat 1·76, total ash 2·41 g., Ca 22, Fe 17·2, P 72 and Cu 0·14 mg. per 100 g. The fat contained 2660 I.U. vitamin A per g. The snail is considered a valuable protein food.—D. Duncan.

FOODSTUFFS OF VEGETABLE ORIGIN

General

239

OYENUGA, V. A. **Nigeria's feeding-stuffs. Their composition and nutritive value.** *Univ. Coll., Ibadan, Fac. Agric. Tech. Bull.* No. 1, July 1955, pp. 53.

Analytical data are presented for dry matter, crude and total protein, fat, fibre, total and silica-free ash and N-free extractives in 105 foods and feedingstuffs, almost all of vegetable origin. Digestible nutrients, except protein, which was estimated chemically, were calculated from the data by the use of coefficients obtained elsewhere. Over half of the bulletin is devoted to notes on the materials analysed and the plants from which they are obtained. Scientific names are given for all and dialect names for some.—D. Harvey.

240

OYENUGA, V. A. **The composition and nutritive value of certain feedingstuffs in Nigeria. 1. Roots, tubers and green leaves.** *Empire J. Exp. Agric.*, 1955, **23**, 81–95. [Div. Animal Nutrit., Fac. Agric., Univ. Coll., Ibadan.]

See preceding Abst.

241

SCHAMBYE, P. and JACOBSEN, I. **Cobalt content in some Danish soils, crops, fertilizers and concentrates.** *Roy. Vet. Agric. Coll., Copenhagen, Yearbook* 1955, 53–77.

Total Co was estimated in samples of surface soils and profiles from Jutland, in areas in which Co deficiency in cattle had been reported and in healthy areas. They represented the 3 main Danish soil types, clay, heath plain sand and diluvial sand. In 12 podsol profiles taken from deficient areas in 1949 the surface soil contained from 0 to 1·16 p.p.m. Co. The Co content of the leached layer increased downwards to the hardpan, which had the highest Co content. In samples from an experimental field in which plots had been manured with either farmyard manure or artificial fertilisers since 1894, the soil treated with farmyard manure contained 1·22 p.p.m. Co, that treated with artificial fertilisers 0·96 and unmanured soil 0·80 p.p.m.

In 1951 soil, pasture and field crop samples were taken from 20 areas, including those where soil profiles had been studied earlier. Co contents as low as 0·2 to 1·5 p.p.m. in heath sand and diluvial sand were not associated with signs of deficiency in cattle. There was little or no direct relation between soil Co and pasture Co, but crops grown on light and acid soil contained more Co than those from neutral soil. The Co content of grass ranged from 0·04 p.p.m. [given as 0·01 in summary] on a sandy loam to 0·21 p.p.m. on a heath sand area [the values are not given in relation to the occurrence of disease in cattle]. Oats, barley and rye contained even less Co than grass, from 0 to 0·07 p.p.m., with little difference between grain and straw. Beet pulp contained from 0·003 to 0·33 p.p.m. and beet leaves from 0·05 to 0·33 p.p.m.

Concentrates were also examined. The highest values for Co were found in coconut and groundnut meals ; soya bean meal and sunflower meal had low values. The concentrates were richer in Co than the grass, local cereals and beet pulp examined. Fertilisers contained little Co and did not contribute much to the Co content of the soil.

DE LANGE, P. and HINTZER, H. M. R. **Studies on wheat proteins. 1. Polarographic determination of the apparent sulfhydryl content of wheat proteins. 2. Significance of sulfhydryl groups and disulfide bonds for baking strength.** *Cereal Chem.*, 1955, **32**, 307–313; 314–324. [Cereals Dept., Central Inst. Nutrit. Res. T.N.O., Wageningen, Netherlands.]

1. Solutions of gluten and water-soluble protein from wheat flour were dispersed in a medium containing gelatine, NH_4OH and $CoCl_2$ and examined polarographically. The apparent sulphydryl content was estimated by measuring the wave height and comparing it with that from a standard solution of cysteine. Expressed as cysteine, values for 13 varieties of Dutch wheat ranged from 0·28 to 0·61 and from 0·46 to 2·50 per cent. for gluten and water-soluble protein.

2. The cystine content was calculated from polarographs of the hydrolysed and unhydrolysed proteins. Baking tests and redox potential measurements of flour suspensions with and without cysteine and potassium persulphate indicated that the ratio of sulphydryl to disulphide in the flour protein may influence the improving action of potassium persulphate.—A. Hepburn.

Roots

249

BOSMAN, J. C., BAKERMANS, W. A. P. and SCHEYGROND, W. Enkele gegevens betreffende het eiwitgehalte van bieten. [**The protein content of beet.**] *Versl. Landbouwk. Onderzoek.*, 1951, No. 57.14, pp. 24. English summary.

According to the list of named varieties of fodder beets issued by the Central Bureau of Animal Feeding, protein content varies with dry matter (DM), but when beet crops are arranged in groups by dry matter content, protein and DM vary inversely. Since 1940 a total of 1630 samples of beet have been analysed: sugar beet 184, fodder-sugar beet 175, Groenkragen (high DM) 483, Groenkragen (low DM) 119, Barres beet 283 and unidentified 386. The records are analysed statistically with reference to the relation between DM and crude protein (inverse second degree relation for all data together); digestibility with pepsin and HCl of the crude protein (increase with percentage crude protein in DM to about 10 per cent. DM and 80 to 85 per cent. digestibility); relation between percentage dry matter and digestible crude protein in fresh substance (inverse, in general, big differences between groups). Regression equations and correlation coefficients are given. In the order of groups above, the following new percentage values are proposed: DM 23·0 for sugar beet, 20·0, 15·0 and finally 12·5 for low DM varieties; digestible crude protein in fresh substance 0·7 for the first three and 0·6 for the last; starch equivalent 16·0, 13·8, 10·3 and 7·9.

If for high DM varieties a yield of roots of 75,000 kg. per hectare and for low DM varieties one of 90,000 kg. is assumed the yields of digestible crude protein per hectare are 525 and 540 kg. and of starch equivalent 7725 and 7110 kg., so that there is little reason to prefer the high DM types on the ground of yield per hectare.—I. Leitch.

250

MURTHY, H. B. N. and SWAMINATHAN, M. **The nutritive value of different varieties of sweet potato.** *Current Sci.*, 1954, **23**, 14. [Central Food Tech. Res. Inst., Mysore.]

Energy value, proximate composition, and Ca, P and carotene contents are tabulated for 2 Indian varieties of sweet potato with white flesh and 3 American varieties with orange flesh. Since the former contained no carotene and the latter from 5·4 to 7·2 mg. per 100 g. fresh material, the introduction of American varieties seems desirable.

ERRERA, G. Ricerche e considerazioni sull'erbaio di Brassica chinensis L. (cavolo cinese). [**Forage from *Brassica chinensis*, L. (Chinese cabbage).**] *Riv. Zootec.*, 1955, **28**, 208–214. [Ist. Zootec. Gen., Fac. Agrar., Piacenza.]

In 6 field trials Chinese cabbage gave yields ranging from 442 to 590 quintals per ha. [17·5 to 23·5 tons per acre]. A seed rate of from 2·5 to 1·5 kg. per ha. [2·2 to 1·3 lb. per acre] sown in rows

50 to 60 cm. [19·5 to 23·5 in.] apart gave the best results. Dry matter of the forage ranged from 7·03 to 8·50, average 7·77 per cent. and crude protein from 1·24 to 1·79, average 1·48 per cent. When sown on suitable soil it produced slightly more feed per ha. than rape, and in feeding trials with dairy cattle the two could be interchanged without affecting milk production. Chinese cabbage was less laxative than rape. It grew more quickly than rape; when sown at the beginning of August it could be cut at the end of October, and could then be grown between a summer harvest and an autumn or winter sowing. It responded well to organic or inorganic fertilisers, especially potash.—T. D. Bell.

Legumes

252

RADHAKRISHNAN, A. N., VAIDYANATHAN, C. S. and GIRI, K. V. **Nitrogenous constituents in plants. 1. Free amino acids in leaves and leguminous seeds.** *J. Indian Inst. Sci.* [*A*], 1955, **37,** 178–194. [Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

Free amino-acids were estimated by paper chromatography in ethanolic extracts of leaves. Leaves of the citrus group, *Citrus decumana*, *C. medica*, *C. acida* and *C. aurantium*, contained large quantities of proline. These species and *Atriplex hortensis*, *Trigonella foenum graecum*, *Murraya koenigii*, *Piper betel*, *Mentha piperita*, *Amaranthus gangeticus*, *Sesbania grandiflora* and *Coriandrum sativum* were comparatively rich in asparagine, glycine, aspartic acid, glutamic acid and alanine. The last 3 edible leaf species contained all the essential amino-acids, but the others lacked some of them. Diseased leaves of *C. aurantium* contained only traces of glutamic and aspartic acids.

Free amino-acids were estimated in the seeds of field bean (*Dolichos lablab*), horse gram (*D. biflorus*), green gram (*Phaseolus radiatus*) and Bengal gram (*Cicer arietinum*). Most amino-acids in green gram increased on germination. Asparagine did not appear until after 48 hr. and then most of the amino-acids expressed as a percentage of total N sharply decreased. Several unknown ninhydrin-positive compounds were present in both seeds and leaves.—A. Hepburn.

GRINDLEY, D. N. and AKOUR, A. A. **The seed oils of *Bombax sessile* and of *Lupinus termis*.** *J. Sci. Food Agric.*, 1955, **6,** 461–465. [Wellcome Chem. Labs., Med. Serv., Minist. Health, Khartoum, Sudan.]

Analytical data are given for the composition of the seeds and the properties of the oils. It is suggested that the oil from *Bombax sessile* might replace palm oil in all its uses; it has the advantage of containing no lipoclastic enzyme to cause deterioration. The non-fatty residue might serve as a cattle feed. The seeds of *Lupinus termis* are eaten by the people of the Sudan, providing a valuable source of protein (34·8 per cent. in the kernel). The oil content is only 9 per cent. Alkaloids are present, so that the seeds should be soaked in water before use.—J. S. Thomson.

HURTADO CERVANTES, J. L. Análisis bromotológico del Solanum Licopersicum "tomate" y microbiológico de la salsa de tomate. [**Bromatological analysis of *Solanum lycopersicum*, the tomato, and microbiology of tomato sauce.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 109–117. [Lab. Invest. Agric.]

Two varieties of tomato commonly grown in Peru had the following average composition: moisture 92·99, protein 1·12, carbohydrate 2·95, ether extract 0·29 and ash 0·52 per cent. In 100 g. fresh material there was 23·5 mg. vitamin C and 0·3 mg. carotene. The dried seeds contained 37·5 per cent. oil.

Purées were made with the addition of 15 per cent. NaCl, 10 per cent. NaCl and 50 mg. Na benzoate per 100 g., or 5 per cent. NaCl and 100 mg. Na benzoate. Bacteriological examination of these and of 2 purées obtained from local markets showed that only in the sample prepared with 10 per cent. NaCl and 50 mg. Na benzoate was the bacterial count after incubation for 48 hr. below 50,000 per g., considered a safe level. There is no law in Peru controlling the levels of preservatives used, or the sale of unsuitable tomato purée. Regulations which should be enforced are suggested.—T. D. Bell.

For part 2 see Abst. 4733, Vol. 25.

3. The approximate amino-acid composition of proteins of hay made from alfalfa, red clover, timothy and orchard grass cut at maturity and alfalfa cut at different stages was quantitatively estimated by 2-dimensional paper chromatography. There was evidence that the haymaking process, stage of growth and species may affect the amounts of methionine, tyrosine, proline, phenylalanine and glycine, but there were only slight changes in most other amino-acids.

Seeds of *Trifolium pratense*, *Medicago sativa* and *Dactylis glomerata* and the seeds and thallus of *Galega officinalis* contained citrulline. This suggests that citrulline is relatively widespread in plants.

4. Amino-acids were estimated by paper chromatography in hydrolysed ethanolic extracts of alfalfa hay cut at different stages of growth on unmanured land and in unhydrolysed extracts of mature alfalfa, red clover, timothy and orchard grass hays grown on manured land. Hydrolysed extracts of fenugreek (*Trigonella foenum graecum*, L.) seeds and mature hays were examined semi-quantitatively for amino-acids.

The amino-acids in alfalfa decreased with increasing age. Aspartic acid, glutamic acid and leucine(s) were present in greatest quantity. Mature alfalfa contained most aspartic acid, glutamic acid, alanine and proline but as free amino-acid it contained most asparagine, serine, glycine, alanine and proline. The mature hays differed in amino-acid composition. Fenugreek seeds contained few free amino-acids. Others were liberated after hydrolysis.—A. Hepburn.

271

PARISH, D. H., COEY, W. E. and ROBINSON, K. L. **The chemical composition of cocksfoot S143 at successive stages of growth, as influenced by fertiliser treatment. 1. Effect of low and high levels of nitrogen fertiliser on the proximate composition.** *Res. and Exp. Rec. Minist. Agric. N. Ireland*, 1952–53 (1955), **3**, 46–54.

A stand of cocksfoot S143 sown the previous summer was divided into 3 replications of 12 plots of which half were dressed with 5 cwt. Nitro-chalk per acre on 24 April. The plots, one treated and one untreated, were cut a fortnight later and each subsequent week for 5 weeks. Yields and proximate compositions were estimated.

In the experimental plots the percentage dry matter was less and the yield of dry matter and the percentage and yield of crude protein were greater than in the untreated plots. The percentage of crude protein decreased with subsequent cuts and the yield of crude protein increased until the fourth cut and then declined slightly. The Nitro-chalk increased the yield of crude protein, but could not prevent this falling off as the grass matured. The yield of dry matter also increased with time. The percentage of crude fibre was similar in control and experimental plots, which suggested that they had the same proportion of leaf to stem. The percentage of crude fibre increased with time, and the application of nitrogen did not appear to delay maturation. The true protein was consistently 80 per cent. of the crude protein, indicating that the protein had not deteriorated because of the fertiliser.—T. D. Bell.

272

HENDERSON, J. L. and DAVIES, R. O. **The yield and composition of mixed cereal-legume crops at different stages of growth. 1.** *Empire J. Exp. Agric.*, 1955, **23**, 131–144. [Univ. Coll. Wales, Aberystwyth.]

In a trial repeated in 3 consecutive years, oats, field peas and spring beans were grown, separately or all together, in experimental plots. They were cut at 7 equal intervals, the first when the oats were 1 ft. high, the peas in full vegetative state and the beans 10 in. high, and the last when all were fully ripe. Yields of dry matter and crude protein were estimated. At the last stage yields of the whole crop as cut were compared with yields after harvesting and threshing.

The highest yield of dry matter was from the mixture, and of crude protein from the peas. The best stage of cutting for silage of any of the crops was stage 4, when the oat grains were milky and the straw was beginning to be predominantly yellow, when the earliest pods on the peas were beginning to develop and the foliage was dark green, and when the seeds had formed in the most

advanced pods of the beans and the foliage was still dark green. After this stage yield of dry matter increased but crude protein decreased. Threshing under experimental conditions caused losses of dry matter and protein, and the grain obtained supplied less starch equivalent and digestible crude protein per acre than the silage made from the crop when cut at stage 4. When harvested under field conditions the losses were even greater. The contribution of the beans to both dry matter and crude protein in the mixture was small, and since they did not fulfil the purpose for which they were intended, namely, acting as supports for the peas, the value of including them was doubtful.—T. D. Bell.

273

THOMAS, B., HOLMES, W. B. and CLAPPERTON, J. L. **A study of meadow hays from the Cockle Park plots. 1. Proximate constituents and digestibility. 2. Ash constituents.** *Empire J. Exp. Agric.*, 1955, **23,** 25–33 ; 101–108. [King's Coll., Univ. Durham, Newcastle upon Tyne.]

1. Hays from 13 plots which had been given different manurial treatments for over 50 years were analysed. The treatments ranged from annual application of farmyard manure and artificial fertilisers to no manure of any type. All plots were cut for analysis on the same day. Digestibility trials of the hay from 4 plots were made with sheep.

On the basis of crude protein, digestible crude protein and calculated starch equivalent, the quality of the hay from plots which had been treated worst from the manurial point of view was highest. Digestibility trials confirmed the analytical results. It was thought that the stage of growth and the botanical composition of the swards were the main reasons for the results obtained. Yield was inversely related to quality.

2. Analysis of the silica-free ash of the hays showed that the percentages of Ca, P, K and Zn were directly influenced by the amounts of these elements supplied by the manurial treatment. No relation was found between treatment and Mg, Fe, Mn or Co content, but Na was low when no basic slag had been applied and high when it had, and basic slag also increased the Ca content. The P content of the ash was positively and the Mn negatively correlated with the acidity of the soil. When the hay contained a high proportion of weeds and clovers the Ca, Co, Mg and Zn contents of the ash were high. The highest Cu content resulted from dressing with farmyard manure.

274

BRANDSMA, S. Over de minerale bestanddelen en hun onderlinge betrekkingen in weidegras van normale bedrijven. [**Mineral components and their interrelations in pasture on normal farms.**] *Meded. Landbouwhogesch. Wageningen*, 1954, **54,** No. 6, 245–309. English summary.

Data are presented in detail for 14 farms, 8 on sand and 6 on clay, where 10 samples of pasture were taken between 1 May and 1 October, 1952. K, Na, Ca, Mg, Cl, S, P and Cu were estimated and tables give the values at the several dates, general averages and averages by soil type. Crude protein was also estimated. Graphs show the seasonal changes for farms on sand and clay separately. In general there was little or no difference, by soil type, in crude protein or P ; all other minerals except K and Ca were less in pasture from sandy soil. Sandy soil showed a higher excess of total base and a higher alkali alkalinity. For the total of 126 samples, the range and mean for Cu in mg. per kg. dry matter (DM) were 5·2 to 15·2 and 10·6. The mean for pasture on clay was 11·7 $\pm$ 1·8 and on sand 9·8 $\pm$ 1·9 mg. Cu per kg. DM.

Correlation coefficients and diagrams show the relation between the several constituents and for comparison earlier data for pasture on which grass tetany occurs, and some other samples, are shown. Tetany pastures have relatively high K and total alkalinity and relatively low Ca and earth alkalinity.

I. Leitch.

275

RØYSET, S. Forsøk med magnesium og aukande mengd kopar til eng. [**Experiment with magnesium and increasing amounts of copper on leys.**] *Forskning og Forsøk Landbruket*, 1955, **6,** 131–140. [Stat. Forsøksgard, Furenes.] English summary.

The ley studied was on peat reclaimed in 1941. Four alternative fertiliser treatments were given to 16 plots in 1947 and hay was cut twice a year in 1947, 1948 and 1949. All the plots received Nitro-chalk, superphosphate and ammonium sulphate, and, per decare, 3 kg. manganese sulphate and 1 kg. borax ; 4 received also 3 kg. and 4 received 6 kg. copper sulphate per decare, 4 had 6 kg. copper sulphate and 10 kg. magnesium sulphate per decare, and 4 only the common treatment.

The Cu content of the hay rose with the amount of Cu supplied, from 4·0 mg. per kg. when no Cu was given to 10·4 mg. per kg. on the plots given 6 kg. $CuSO_4$ per decare. The biggest increase in yield was from the plots given 3 kg. $CuSO_4$ per decare, and in the third year only from those given 6 kg. ; it is postulated that the larger application was excessive. The plot given Mg gave in 1947 an increase attributed to Mg, in 1948 a poor increase and in 1949 an increase attributed to Cu.

The ley consisted originally of clover and grasses, but by the third year there was no clover. (From summary.)—D. Duncan.

276

CURNOW, D. H. and ROSSITER, R. C. **The occurrence of genistein in subterranean clover (*T. subterraneum*, L.) and other trifolium species.** *Austral. J. Exp. Biol. Med. Sci.*, 1955, **33**, 243–248. [Dept. Agric., Perth, W. Australia.]

In every single one of 123 strains of subterranean clover (*Trifolium subterraneum*, L.), 74 from Australia and 49 from overseas, mainly from the Mediterranean region, genistein or some closely related compound was detected by paper chromatography, from its R_F value and the pink colour developed with $FeCl_3$ (Abst. 1638, Vol. 25). The chance of finding a genistein-free strain of this valuable clover seems small. Of 17 other clovers examined, *T. globosum* contained about as much as *T subterraneum*, *T. campestre* (hop clover) and *T. pratense* (red clover) rather less.—W. M. Deans.

277

LAKKE GOWDA, H. S. **Studies on jola or jowar (*Andropogon sorghum*) as cattle fodder. 3. Hydrocyanic acid and phytic acid phosphorus content of different varieties of jola fodders at different stages of growth.** *Indian J. Dairy Sci.*, 1955, **8**, 47–52. [Mysore Serum Inst., Bangalore.]

For previous parts see Absts. 4090, Vol. 23; 4285, Vol. 24.

The HCN content of 4 different varieties of jowar (Kati, White, Ibbani and Red) was highest at the third week of growth, the value in the whole plant ranging from 13 to 32 mg. per 100 g. dry matter. The leaves had a higher content than the stems. From the third to the seventh week there was an abrupt fall in HCN content and by the 15th week only traces were present.

Phytic acid P was present in relatively small amounts in the early stages of growth, 30 to 40 mg. per 100 g. dry matter, but increased steadily, reaching a value of 122 mg. per 100 g. by the 17th week. Total P decreased steadily during growth.—J. S. Thomson.

MITCHELL, T. J., IRVINE, L. and SCOULAR, R. H. M. **An examination of Scottish heather honey. 2.** *Analyst*, 1955, **80**, 620–622. [Dept. Tech. Chem., Royal Tech. Coll., Glasgow.]

In continuation of previous work (Abst. 312, Vol. 25), 25 samples of heather (ling, *Calluna vulgaris*) honey and 1 of bell heather (*Erica cinerea*) honey of the year 1952 were examined.

For heather honey *p*H ranged from 4·20 to 5·36 and moisture, deduced from the refractive index, from 16·0 to 24·8 per cent., mean 20·2. Colloid formed from 1·35 to 3·90 per cent. of the dry matter and the N content of the colloid ranged from 9·08 to 11·85 per cent., mean 10·25, corresponding to a protein content of about 64 per cent. The thixotropic ratio ranged from 2 [1 on p. 621] to 100. In some samples, but not all, high colloid content went along with high thixotropic ratio.

The sample of bell heather honey had *p*H 4·14, moisture 16·1 per cent., colloid 0·80 per cent. of the dry matter, N 9·60 per cent. of the colloid; the thixotropic ratio was 2.—W. M. Deans.

YAMAGATA, S., ARAI, I., UNOURA, K., ARATANI, T., MIURA, K. and OTOMO, K. Experimentelle Studien über die Funktion des reticuloendothelialen Systems. 5. Einfluss verschiedener Hormone und Vitamine auf die Funktion des RES und der Leber. [**Experimental studies on the function of the reticulo-endothelial system. 5. Effect of different hormones and vitamins on the function of the reticuloendothelial system and of the liver.**] *Tohoku J. Exp. Med.*, 1955, **61,** 113–125. [Med. Klin., Tohoku Univ., Sendai.]

The effect of the substances tested was judged by the changes in the Congo red index and in the prothrombin time, as previously described (*Tohoku J. Exp. Med.*, 1954, **59,** 257). The Congo red index was taken as measuring the activity of the reticuloendothelial system and the prothrombin time as the measure of liver function. Each trial was on 2 rabbits. Pituitary, adrenal and sex hormones, thyroxine and insulin were tested. Except for the adrenal cortical hormone, large doses of Amolysin and a testicular hormone preparation, they all reduced the Congo red index, showing the activity of the reticuloendothelial system to be increased; the prothrombin time was not affected except that it was increased by adrenal cortical hormone and the sex hormones tested. Vitamins A, D, B complex, C and K all decreased the Congo red index, but their effect on the prothrombin time varied. Luminal given alone increased the Congo red index but decreased the prothrombin time; given with anterior pituitary extract it did not alter the effect of the hormone but, given with vitamins A and D, it cancelled their stimulating effect on the reticuloendothelial system. From the results it was concluded that the reticulo-endothelial system is stimulated directly by the anterior pituitary hormone but indirectly, through the vegetative nervous system, by the vitamins.—L. Wills.

288

The effect of variety, curing, storage, and time of planting and harvesting on the carotene, ascorbic acid, and moisture content of

sweet-potatoes grown in six Southern States. *N. Carolina Agric. Exp. Stat. S. Cooperative Ser. Bull.* No. 30, October 1953, pp. 48.

The study was made over 7 years in 15 locations. One variety of sweet potato was always grown to provide a common standard of performance. Vitamin C was estimated in the reduced form as ascorbic acid, and carotene by the method of Moore and Ely (Abst. 1954, Vol. 11).

Carotene ranged from 0·5 in the light-coloured varieties to 44·6 mg. per 100 g. dry weight in the more pigmented ones. There were wide differences from year to year within locations but greater differences between locations, some of which seemed consistently associated with high or low values for carotene. Ascorbic acid concentration showed similar variations and ranged from 66·8 to 110·3 mg. per 100 g. The dates of planting and harvesting had no effect on carotene content, but roots from a first harvest contained more ascorbic acid when the planting was late than when early. In general, ascorbic acid decreased after 156 days of growth. Curing the roots for from 7 to 15 days at 75° to 85° F. caused shrinkage and about 20 per cent. of the ascorbic acid was lost. Storage for 4 months at 52° F. and at relative humidity from 75 to 85 per cent. about doubled the loss. Carotene content was not affected by curing or storage.

Moisture content varied widely both within and between locations for a single variety and had a mean value of 71·7 per cent. It remained relatively constant during curing and storage. About 5 per cent. of the weight was lost during curing and a further 7 per cent. after storage.

The yield of marketable roots varied considerably and was greatly influenced by environmental conditions. Allgold and Bunch Porto Rico had the highest yields.—A. Hepburn.

PATTON, M. B. and GREEN, M. E. **Cabbage. Factors affecting vitamin values and palatability. 1. Compilation of National Cooperative research findings on cabbage.**

GREEN, M. E. **2. Review of literature on cabbage.** *Ohio Agric. Exp. Stat. Res. Bull.* No. 742, April 1954, 5–52 ; 53–96.

1. The results, mostly published already, of researches on raw and cooked cabbage under the auspices of the National Cooperative Project on conservation of the nutritive value of foods at 20 agricultural experiment stations and at the U.S. Regional Vegetable Breeding Laboratory, Charleston, S.C. are summarised. Most of the work was on ascorbic acid but some results for vitamin B_1, riboflavin and Ca are given. A few pages are devoted to dehydrated cabbage and sauerkraut. Among the effects studied were those of variety, season, maturity, storage, cutting and details of cooking method.

2. The literature published in English between 1935 and the middle of 1952 is similarly summarised. There are 102 references without those on dehydrated cabbage and sauerkraut.

W. M. Deans.

290

POROTNIKOFF, O. Statens vitamin-laboratoriums undersøgelser af vitaminindholdet i danske levnedsmidler (1947–1953). [**Studies of the State Vitamin Laboratory of the vitamin content of Danish foods (1947–53).**] *Statens Husholdningsråds Faglige Medd.*, January-February 1954, Nos. 1–2, 1–7.

The causes of variation in the vitamin content of foods are summarised. The investigation was planned so that allowance was made for the more important causes of variation, but differences due to different Danish soils were not allowed for, since only the Copenhagen market was tapped ; within it, sampling by area and shop was wide. Preparation for analysis took into account possible inequalities of distribution within a sample. The results are expressed in terms of the edible portion of foods as purchased in the open market. Values for vitamin C are set out in a table. Foods known not to contain vitamin C were not tested. Values entered as 0 represent samples that were analysed but in which none was found. Estimation was by the 2 : 6-dichlorophenolindophenol method checked against a spectrographic method (see Abst. 181, Vol. 23). Dehydroascorbic acid was present only in amounts that did not exceed the possible error of the method and so was not distinguished. A few biological tests were made for comparison.

Certain comments on the table are made. Milk contained more vitamin C between October and March than between April and October. Vegetables showed seasonal differences and losses over the winter ; some, such as spinach, showed wide variations not referable to season. Fruits varied greatly with variety. On the average, Danish did not differ from imported fruit. Of jams, strawberry and blackcurrant had most vitamin C.

I. Leitch.

291

LIECK, H. Statens vitaminlaboratoriums undersøgelser af nikotinsyreindholdet i danske naeringsmidler. [**Studies at the State Vitamin Laboratory of the nicotinic acid content of Danish foods.**] *Statens Husholdningsråds Faglige Medd.*, October-December 1954, Nos. 10–12 ; 41–46.

Methods of collection and sampling were described in the preceding report on vitamin C. Nicotinic acid was estimated with *Lactobacillus arabinosus* by a method closely similar to that

described in the U.S. Pharmacopoeia (1947, XIII, p. 669).

Comments on the table are that there was little seasonal variation in the nicotinic acid content of vegetables and little destruction in cooking (another publication to follow). Vegetables of greatest value were mushrooms, green cabbage, green peas, parsnip, cress and potato. Fruit contained little nicotinic acid ; elderberries had most. Meat was the main source and account must be taken of its fat content. Of fish, the best were eel, gar, salmon, mackerel and tunny.—I. Leitch.

292

HJARDE, W. Statens Vitamin-laboratoriums undersøgelser af B_1-vitaminindholdet i danske naeringsmidler. [**Studies at the State Vitamin Laboratory of the vitamin B_1 content of Danish foods.**] *Statens Husholdningsråds Faglige Medd.*, March-April 1955, Nos. 3–4, 9–16.

Methods of collection and sampling were as described for estimation of vitamin C and nicotinic acid. Total vitamin B_1 was estimated by a modification of the thiochrome method described elsewhere (Hjarde, *Thesis*, 1950).

The values given for cereal products refer to them as they were on the market up to the beginning of 1954, and differences reflect differences in milling practice. After April 1954, from which date 500 μg. vitamin B_1 per 100 g. was to be added to wheat flour and semolina, all the present values are subject to revision. Bread, cakes and biscuits are all affected. In the interval a correction based on the amount of flour in the several products should be made. The amounts are shown in the table.

Some vegetables showed wide variations ; green peas had most vitamin B_1. Fruits supplied little and those treated with sulphite none. The fat content of meat had to be taken into account. Pig meat was outstandingly high. Other specially valuable foods, in terms of vitamin B_1, were yeasts and nuts, except coconut.—I. Leitch.

VITAMIN A

293

ROUSSEAU, J. E. (Jr.), EATON, H. D., BEALL, G. and LUCAS, H. L. (Jr.) **A multiple regression study of the Carr-Price reaction for vitamin A in the presence of carotene.** *J. Dairy Sci.*, 1955, **38,** 902–903. [Storrs Agric. Exp. Stat., Conn.]

Standard solutions of vitamin A alcohol, and of carotene containing 90 per cent. of the β-isomer, were prepared and mixed to give concentrations of vitamin A ranging from 0 to 9·6 μg. and of carotene from 0 to 32 μg. per 10 ml. solution. The transmittance of the solutions was measured and varied from about 10 to 100 per cent. at 440 mμ. and from 20 to 100 per cent. in the product of the $SbCl_3$ reaction at 620 mμ. The estimations were made on each of 4 consecutive days. A model equation was fitted to the data ; none of the coefficients of the terms involving products of vitamin A concentration and carotene concentration were significantly different from zero, thereby apparently justifying the validity of the assumption of additivity of the colour densities of the 2 substances in the correction of Dann and Evelyn. Beer's law was found to hold for solutions of carotene but not of vitamin A. The divergence from the theoretical of solutions of vitamin A accounted for only 0·1 per cent. of the variance due to the concentration of vitamin A. When it was assumed that Beer's law held for both vitamin A and carotene it was found that carotene produced about 1/17th of the colour density of vitamin A in the $SbCl_3$ reaction. It is suggested that multiple regression analysis may be used to estimate the magnitude of the interference caused by carotenoid pigments when the $SbCl_3$ reaction is used for biological material.—I. M. Sharman.

DUNCKLEY, G. G. and MACFARLANE, Y. J. **Partition chromatography of vitamin-A-alcohol and its application to the non-saponifiable matter from cod-liver oil.** *J. Sci. Food Agric.*, 1955, **6,** 559–564. [Dept. Nutrit. Res., Med. Sch., Dunedin, N.Z.]

Reversed-phase partition columns as prepared by Howard and Martin (Abst. 1353, Vol. 20) with kieselguhr which had been made unwettable by exposure to dimethyldichlorosilane vapour and with medicinal paraffin as the stationary phase were used. For a column 6 cm. high and 15 mm. in diameter, 6 g. of the silane-treated kieselguhr was used. Before use the columns were washed with 90 per cent. aqueous methanol. The unsaponifiable material of cod liver oil was applied to the column, and developed with aqueous methanol, ethanol or *iso*propanol. Separation of vitamin A from material with irrelevant absorption was achieved by development with 25 per cent. aqueous ethanol followed by 70 per cent. aqueous methanol.—R. J. Ward.

295

SMITH, H., BEAUCHENE, R. E., PARRISH, D. B. and MITCHELL, H. L. **Detection of**

N, N'-diphenyl-p-phenylenediamine (DPPD) in dehydrated alfalfa and in mixed feeds. *J. Agric. Food Chem.*, 1955, **3**, 788–789. [Kansas Agric. Exp. Stat., Manhattan.]

A test is described for the presence of the antioxidant DPPD, which interferes with the estimation of carotene.

To 2 g. alfalfa meal were added 30 ml. 1 : 1 hexane-acetone. The suspension was stirred, 2 g. activated magnesia were added with stirring and the supernatant solution was filtered. The filtrate was treated with 5 ml. of 1 : 3 HCl and a drop of 0·25 per cent. copper sulphate. A blue colour in the aqueous layer showed the presence of DPPD in the sample. For mixed feeds the test was much the same but a 10 g. sample was extracted and the supernatant solution was treated a second time with magnesia before filtering.

The test detected concentrations of DPPD as low as 6 p.p.m. in mixed feed. In a more sensitive, but less specific, test the filtered solution obtained as before was evaporated and the residue was treated with concentrated HNO_3. The solution turned blue, then red.—V. H. Booth.

POWELL, L. T., KRAUSE, R. F. and SANDERS, P. L. **The purification of milligram quantities of vitamin A.** *Arch. Biochem. Biophys.*, 1955, **57**, 306–311. [Dept. Biochem., Sch. Med., W. Virginia Univ., Morgantown.]

The livers of normal rats and of rats which had been given different amounts of vitamin A by mouth were homogenised in 2 N alcoholic KOH and the mixture was refluxed for 30 min. The unsaponifiable fraction was extracted with light petroleum and vitamin A was estimated by the $SbCl_3$ method. The vitamin A content of the livers ranged from 489 to 14,900 μg. Sterols were removed by precipitating with digitonin, and vitamin A was estimated again in a portion of the sterol-free extract. The remainder of the extract was adsorbed on alumina, the unadsorbed impurities were removed by washing the column with light petroleum and the vitamin A was eluted with a 1 : 1 mixture of light petroleum and ethyl ether. The final estimation was made spectrophotometrically and the purity was measured by the ratios $E_{310\ m\mu}/E_{325\ m\mu}$ and $E_{350\ m\mu}/E_{325\ m\mu}$. With pure vitamin A the ratios were 0·87 and 0·41 ; the average ratios for the liver extract were $0{\cdot}87 \pm 0{\cdot}02$ and $0{\cdot}41 \pm 0{\cdot}01$ with $E\,^{1\ per\ cent.}_{1\ cm.}$ ranging from 1605 to 1795. Recoveries ranged from 68 to 89 per cent. of the amount found by the $SbCl_3$ method.—R. J. Ward.

298

WALD, G., BROWN, P. K., HUBBARD, R. and OROSHNIK, W. **Hindered *cis* isomers of vitamin A and retinene: the structure of the *neo*-β isomer.** *Proc. Nat. Acad. Sci., Washington*, 1955, **41**, 438–451. [Biol. Labs., Harvard Univ., Cambridge, Mass.]

299

LAMBERTSEN, G. and BRAEKKAN, O. R. **A possible new vitamin A_1 isomer in the eyes of crustaceans.** *Nature*, 1955, **176**, 553–554. [Govt. Vitamin Lab., Norwegian Fish. Res. Inst., Bergen.]

The content of vitamin A in the eyes of the deep-sea prawn *Pandalus borealis* was estimated by a chromatographic procedure to be 150 I.U. per g. No vitamin A_2 was present. The ultraviolet absorption curve departed to the left from the expected curve for vitamin A_1. The maleic anhydride reaction gave 70·6 per cent. recovery, with the *cis*-configuration predominating. Biological potency of the extracted compound was found by Fisher *et al.* (*J. Marine Biol. Assoc. U.K.*, 1952, **31**, 229) to be 50 per cent. compared with the results of the chemical estimations. It is claimed that the results obtained point to a new vitamin A_1 isomer in the eyes of crustaceans, possibly the Δ-3 : 5-di-*cis*-isomer.—I. M. Sharman.

300

AMES, S. R., SWANSON, W. J. and HARRIS, P. L. **Biochemical studies on vitamin A. 14. Biopotencies of geometric isomers of vitamin A acetate in the rat. 15. Biopotencies of geometric isomers of vitamin A aldehyde in the rat.** *J. Amer. Chem. Soc.*, 1955, **77**, 4134–4136 ; 4136–4138. [Distillation Products Indust., Eastman Kodak Co., Rochester, N.Y.]

14. Measurements of growth and storage in the liver of rats were used to estimate the activity of the 5 isomers of vitamin A acetate. The growth experiments compared 2 doses of the test material with 2 similar doses of the U.S.P. Reference Standard. The 3 new isomers, 6-mono-*cis*, 2 : 6-di-*cis* and 2 : 4-di-*cis*, were found to have potencies of 634,000, 688,000 and 679,000 I.U. per g., respectively. Each of them therefore possessed about 23 per cent. of the defined activity, 2,907,000 I.U., of all-*trans*-vitamin A acetate. The mean conversion factor found from 7 estimates of liver

storage and 6 of growth with *neo*vitamin A acetate (2-mono-*cis*) was 1523 and the potency 2,190,000 I.U. per g., or 75·3 per cent. of the activity of all-*trans*-vitamin A acetate. It is difficult to detect the presence of the 6-*cis*- and 2 : 4-di-*cis*-isomers in vitamin A preparations by physical or chemical methods, so it is suggested that biological tests by one of these methods may be used to ascertain the presence of appreciable amounts of these 2 isomers.

15. The biological activity of 5 geometric isomers of vitamin A aldehyde and of α-vitamin A aldehyde was estimated from measurements of rat growth and liver storage with the U.S.P. Reference Standard for comparison. All-*trans* and *neo*-(2-mono-*cis*)-vitamin A aldehyde were found to have the same potency of 3,070,000 I.U. per g. or, on a molar basis, about 91 per cent. of the activity of all-*trans*-vitamin A acetate. The 6-mono-*cis*- and 2 : 6-di-*cis*-vitamin A aldehydes had potencies of 637,000 and 581,000 I.U. per g., respectively, only about 18 per cent. on a molar basis of the activity of all-*trans*-vitamin A acetate. The 2 : 4-di-*cis*-vitamin A aldehyde had an intermediate potency of 1,610,000 I.U. per g. or about 48 per cent. on a molar basis of the activity of all-*trans*-vitamin A acetate. The α-ionone analogue of vitamin A aldehyde had a potency less than 50,000 I.U. per g., the lowest level at which it was tested; in metabolism it was converted into α-vitamin A alcohol and about 39 per cent. of the ingested dose was found in the liver. As about 65 per cent. of all-*trans*-vitamin A acetate when ingested is found in the liver, it follows that the relative efficiency of storage in the liver of α-vitamin A aldehyde was about 60 per cent. It appears, therefore, that although it is inactive as vitamin A, the α-ionone analogue of the aldehyde is reduced, transported and stored like the aldehyde itself.

CURL, A. L. and BAILEY, G. F. **The state of combination of the carotenoids of Valencia orange juice.** *Food Res.*, 1955, **20,** 371–376. [W. Utilisation Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 10, Calif.]

The present study is complementary to work reported earlier (Abst. 338, Vol. 25). Valencia orange juice was filtered, the filter cake was extracted with acetone, the acetone was evaporated and the residue was dissolved in light petroleum. This extract was fractionated in a 100-tube Craig apparatus with light petroleum and 90 per cent. methanol. The fractions were examined colorimetrically and pooled into groups containing carotenoids with no free hydroxyl group, with one, and with 2 or more. Another similar run was made and the grouped extracts were saponified. The 6 solutions were chromatographed on magnesia. The state of combination of the carotenes was studied by comparing the results with the saponified and the non-saponified extracts.

The greater part of the carotenol fraction, as it occurred in the juice, was in the fully esterified form. The carotenols which have no cyclic ether groups, namely, cryptoxanthol, the hydroxy-α-carotene-like fraction, luteol and zeaxanthol, occurred mainly as esters. Epoxides occurred principally as esters, and the isomeric furanoxides were found to a considerably greater extent as free alcohols.

Nineteen of the carotenoids are tabulated and labelled with their probable identity. Two new carotenoids not previously found in nature were discovered. The name trollein is proposed for one, a polyol. The other was probably an ester of a carotenoid acid.—V. H. Booth.

NIESAR, K. H. Ein biochemische Wirkung von Vitamin A. [**A biochemical action of vitamin A.**] *Naturwissenschaften*, 1955, **42,** 392–393. [Inst. Physiol. Ernährung Tiere, Univ. Munich.]

In young rats which had been made deficient in vitamin A the amount of deoxyribonucleic acid and of ribonucleic acid was below normal in the skin, testes, intestines, adrenal glands, diaphragm, heart, brain and thyroid gland. There was little change in the kidneys, and the amount of both substances was greater than normal in the liver

and spleen. In normal rats subcutaneous injection of 1000 I.U. vitamin A as an aqueous emulsion increased the amount of both substances in all the organs mentioned except the thyroid gland, which was not examined.—T. Moore.

MARSH, H. and SWINGLE, K. F. **Blood phosphorus, calcium, and vitamin A in range sheep.** *Amer. J. Vet. Res.*, 1955, **16,** 418–424. [Agric. Exp. Stat., Montana State Coll., Bozeman.]

Blood specimens were obtained over 4 years from breeding ewes on the Chadbourne Sheep Range in south-central Montana in the eastern foothills of the Rocky Mountains. The averages and standard deviations for 517 estimations were, per 100 ml. plasma, P 4·3 ± 0·9 mg., Ca 9·2 ± 1·0 mg. and vitamin A 29 ± 7·3 μg. The specimens were collected from 12 groups of from 30 to 32 animals; 11 of the collections were made during the winter, from October to March. The group of 46 animals from which samples were taken during the summer showed a higher value for P, 5·4 mg. per 100 ml. Values from ewes given a protein concentrate during pregnancy were not significantly different from those for other ewes on the range, not given the concentrate. One group not wintered on the range and given hay and concentrate had a higher vitamin A value of 33 μg. per 100 ml. when estimations were made in March. The carotène content of the grasses on the range generally varied between 1 and 3 μg. per g. but for the species *Artemisia frigida* reached the high value of 24 μg.

ROKKOMES, T. **Experimental hydrocephalus in young rats.** *Internat. Ztschr. Vitaminforsch.*, 1955, **26,** 1–10. [Biochem. Inst., Vet. Coll. Norway, Oslo.] German and French summaries.

A disorder in young rats, characterised by spastic muscle contractions, bloody exudate from the eyes and disturbances in growth of the fur, is described. The disorder proved to be hydrocephalus, the initial sign being a rise in cerebrospinal fluid pressure. The condition occurred when the parent rat was given a diet poor in vitamin A before and during pregnancy and also when a vitamin A supplement, sufficient to prevent the disorder in the young, was reduced while the young rats were less than 18 days old. Experiments suggested that an increase in the intake of fat-soluble vitamins prevented the disorder. The usual supplements of vitamins A, D, E and K were barely sufficient to prevent it, and were not sufficient to prevent a considerable rise in cerebrospinal fluid pressure in the young rats. Additional vitamin A prevented all visible manifestations of the disorder, showing that it was caused by an absolute or relative deficiency of vitamin A.

BLAIZOT, J. and BÉNAC, R. La dépense énergétique chez le rat au cours de l'avitaminose A expérimentale. [**Energy expenditure in the rat during experimental vitamin A deficiency.**] *C.R. Soc. Biol.*, 1955, **149,** 810–813. [Lab. Physiol. Gén., Fac. Sci., Toulouse.]

Numerous measurements of oxygen consumption were made on 22 rats deprived of vitamin A, and on 14 not deprived. Oxygen consumption increased with age and bodyweight, and varied between individuals. For the same age the average consumption of oxygen was from 10 to 25 per cent. greater in the deprived than in the non-deprived. The increase in oxygen consumption was an earlier sign of deficiency than cessation of growth or xerophthalmia.—T. Moore.

310

BERNHARD, K. and HEINZELMANN, F. Untersuchungen über die Resorption durch Gelatine oder Pektin stabilisierter Vitamin-A-Präparate zur Vitaminisierung von Futtermitteln. [**Studies on the absorption of preparations of vitamin A stabilised with gelatine or pectin for use in vitaminising feeds.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26,** 91–95. [Schweiz. Vitamin Inst., Basle.] French and English summaries.

Dry vitamin A as preparations of vitamin A palmitate protected with gelatine or pectin was given to rats. Lymph was collected through a thoracic duct fistula and vitamin A was estimated by the Carr Price method.

When the dry vitamin preparation was given suspended in oil or water, 26·2 and 30·4 per cent., respectively, of the amount given was found in the lymph; 36·2 per cent. was found in the lymph of similar rats given unstabilised vitamin A palmitate in solution in olive oil.

The importance is discussed of protecting vitamin A so that it is stable in feeds and yet easily absorbed from the alimentary tract. It is claimed that the dry vitamin suspended in water is absorbed to the same extent as the unstabilised vitamin, but that, suspended in oil, it is less well absorbed.—V. H. Booth.

KIMBEL, K. H., FISCHER, W. and BÜNTE, H. Untersuchungen über enterale Antibiose bei der Ratte. 7. Resorption von Vitamin A. [**Studies on intestinal antibiotics in the rat. 7. Absorption of vitamin A.**] *Ztschr. ges. exp. Med.*, 1955, **126,** 141–144. [Med. Klin., Univ. Erlangen.]

For previous parts see Absts. 4382, Vol. 24; 2215, Vol. 25.

Of 56 albino rats weighing about 200 g., 16 were given 25 mg. of a water suspension of aureomycin daily for 5 weeks; the rest were untreated. Both groups were given 4000 I.U. of a water-soluble preparation or an oily solution of vitamin A by injection into the stomach, and 4½ hr. later they were killed. The contents of the intestines were washed out with petrol and homogenised with the intestines. The homogenate was filtered through paper and the filtrate was concentrated by drying *in vacuo* at 45° C. The residue was dissolved in chloroform and vitamin A was estimated by the Carr Price reaction. The livers were treated in the same way. The average vitamin A content of the intestines and livers of the rats receiving the water-soluble vitamin A was, respectively, 102 and 267 I.U. for those not given aureomycin and 115 and 204 I.U. for those given aureomycin. For those receiving the oily solution of vitamin A considerable differences were found. The intestines of those not given aureomycin contained on the average 2479 I.U., and of those given aureomycin only 900 I.U. The vitamin A content of the liver of those not given aureomycin was not estimated, but that of the rats given aureomycin was on the average 67 I.U.—R. J. Ward.

Kon, S. K., McGillivray, W. A. and Thompson, S. Y. **Metabolism of carotene and vitamin A given by mouth or vein in oily solution or aqueous dispersion to calves, rabbits and rats.** *Brit. J. Nutrition*, 1955, **9**, 244–267. [Nat. Inst. Res. Dairying, Univ. Reading.]

Rats and calves deprived of vitamin A and normal rabbits were given, orally and intravenously, carotene and vitamin A in oily solution or aqueous dispersion. The dispersions were prepared with and without the surface-active agent Tween 40. When carotene in Tween dispersion was injected into rats and rabbits little or no carotene was found in the blood 24 hr. later. After 5 min. vitamin A alcohol was found in the blood of rats, and later the values rose in the blood of both rats and rabbits. Analysis of carcases of rabbits at intervals after injection showed that most of the carotene disappearing from the blood was destroyed. The results suggest that the intestinal wall was not the site of conversion of injected carotene to vitamin A. When dispersions of carotene without Tween were injected, carotene disappeared rapidly from the blood and was not converted into vitamin A. With calves, carotene dispersed with or without Tween was converted very little, if at all, into vitamin A. The value for carotene in the blood rose and carotene persisted for up to 10 days but the rise did not account for more than half the amount injected. When vitamin A was injected it always appeared in the blood as the alcohol, whatever the dispersion or the species, but never quantitatively. The amount of vitamin A alcohol in the liver rose to about half, but in calves to only about one-tenth, of the dose injected. Appreciable amounts of carotene and vitamin A were found in the lungs of rabbits and calves after injection, but rapidly disappeared.

313

Teichman, R., Helmboldt, C. F., Rousseau, J. E. (Jr.), Jungherr, E. L., Eaton, H. D., Beall, G. and Moore, L. A. **Estimation of vitamin A depletion time in dairy calves.** *Storrs Agric. Exp. Stat. Bull.* No. 301, July 1953, pp. 30.

A ration deficient in vitamin A and carotene was given to 23 Holstein and 15 Guernsey calves aged 105 days, to 14 Holstein calves aged 63 days, and to 14 Holstein calves aged 35 days, until the level of vitamin A in blood plasma was less than 4 μg. per 100 ml. for 2 consecutive weeks. The average depletion time for the 105-day-old Holstein calves was 8·56 weeks, for the 105-day-old Guernseys 7·25 weeks and for the 63- and 35-day-old Holsteins 9·44 and 8·58 weeks, respectively. The linear rate of depletion was characteristic for age and breed but not for depletion time, level of feeding, sex, season or year.

The depletion time taken to reach the 4 μg. level, estimated from the average rates of decrease over the total period of depletion for each group of calves and the average levels of vitamin A in plasma for each calf after periods of from 1 to 4 weeks on the ration, agreed well with the observed values. Estimations based on the rates of decrease of vitamin A in plasma in individual calves or in subgroups during the initial depletion period were not so good.—T. Moore.

314

Byers, J. H., Weswig, P. H., Bone, J. F. and Jones, I. R. **Carotene in the ration of dairy cattle. 1. The influence of long periods of suboptimal carotene intake on the carotene and vitamin A values of the blood, liver, and milk fat of dairy cows.** *J. Dairy Sci.*, 1955, **38**, 657–663. [Dept. Dairy Husb., Oregon State Coll., Corvallis.]

Holstein and Jersey cows which had been kept on a diet providing 50 μg. carotene per kg. bodyweight [daily] were maintained on the same diet or on one providing 130 or 390 μg. carotene per kg. bodyweight [daily]. Carotene and vitamin A were estimated in the blood plasma, liver and milk fat at regular intervals. When the carotene intake was at the 390 μg. rate the vitamin A and carotene content of the blood plasma and liver

did not increase. Repeated injections of 250,000 or 1,250,000 I.U. of vitamin A ester also failed to increase the vitamin A content in the liver of the cows on the lowest carotene intake.—R. J. Ward.

TEICHMAN, R., MORGAN, M. E., EATON, H. D. and MACLEOD, P. **Effect of feeding N, N′-diphenyl-para-phenylenediamine to lactating dairy cows on carotene utilization and incidence of oxidized milk flavor.** *J. Dairy Sci.*, 1955, **38,** 693–695. [Storrs Agric. Exp. Stat., Conn.]

In a first experiment, 4 calves were fed on a ration low in carotene for 13 weeks from the age of 6 weeks. Dehydrated alfalfa meal was then added to the ration so that the daily intake of carotene was about 25·8 mg. per 100 lb. liveweight. After a stabilising period of 2 weeks 0·01 per cent. N, N′-diphenyl-*p*-phenylenediamine (DPPD) was included in the ration for 2 periods of 3 weeks in a simple reversal trial. In a second experiment, 8 lactating cows were selected as producing milk which developed an oxidised flavour within 24 hr. of adding 0·5 p.p.m. of Cu^{++} ions. Each of the cows received 2 g. DPPD daily during 2 periods of 15 days also in a reversal trial. During both experiments milk samples were taken for estimation of sp. gr., fat, carotenoids and vitamin A, and blood specimens for estimation of carotenoids and vitamin A. Administration of DPPD was found to improve utilisation of carotene, and the values for carotenoids and vitamin A were higher in both blood and milk. Organoleptic tests at intervals during the experiments showed that none of the milk samples developed off-flavour attributable to the use of DPPD.—I. M. Sharman.

CHANDA, R., CLAPHAM, H. M. and OWEN, E. C. **The effects of deprivation of carotene and anterior pituitary hormone on the partition of vitamin A in the blood and milk of the cow.** *Biochem. J.*, 1955, **60,** 391–399. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Injection of a proprietary preparation containing the thyrotropic, luteinising and follicle-stimulating hormones of the anterior pituitary was made in Ayrshire cows with and without dietary carotene. Carotene, vitamin A alcohol and vitamin A ester were estimated in the blood and milk of the treated cows and of untreated cows receiving the same diet. The pituitary preparation increased the mean daily output in milk of vitamin A alcohol when carotene was either absent from or present in the diet; the change was greater when it was absent than when it was present. The output of vitamin A ester also in the milk of cows given no green feed was increased by the hormone preparation though no vitamin A ester was found in the blood. The hormone treatment evidently increased the rate of esterification of vitamin A by the mammary gland. It also increased the serum vitamin A alcohol whether or not greenstuff was present in the diet and appeared to accelerate the conversion of dietary carotene into vitamin A in the gut. It is suggested that the results support the hypothesis that the hormone preparation, like thyroxine, accelerated the mobilisation of the liver reserves of vitamin A alcohol into the blood and thence into the milk in both alcohol and ester form.—I. M. Sharman.

317

LE GALLIC, P. Influence du parasitisme sur les fonctions liées à la vitamine A, chez le rat et la souris. [**Effect of parasitic infestation on functions connected with vitamin A in the rat and mouse.**] *C.R. Soc. Biol.*, 1955, **149,** 349–351.

When rats deficient in vitamin A were given liver from normal mice which had been deprived of the vitamin for 15 days their condition improved for more than 20 days. Improvement lasted for less than 4 days, however, if the mice had been deprived of the vitamin for the same period but had been suffering from mange or helminthic infection. Parasitic infestation appeared to interfere with the synthesis of "hormonal vitamin A".—T. Moore.

318

GIROUD, A. and MARTINET, M. Hypervitaminose "A" et anomalies chez le foetus de rat. [**Vitamin A excess and malformations in the rat foetus.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26,** 10–18. [Lab. Embryol., Fac. Méd., Paris.] English and German summaries.

Daily doses of 35,000 I.U. vitamin A acetate or palmitate given to pregnant rats invariably caused the death and resorption of the embryos; with 20,000 I.U. daily for 12 days early in pregnancy litters were carried to term by about half the animals. Severe malformations, which included anencephaly, anophthalmia, microphthalmia and cleft palate, occurred in a high proportion of the surviving embryos taken from rats killed on the 21st day of gestation.—T. Moore.

319

LASNITZKI, I. **The effect of excess vitamin A on mitosis in chick heart fibroblasts *in vitro*.** *Exp. Cell. Res.*, 1955, **8,** 121–125. [Strangeways Res. Lab., Cambridge.]

Hanging drop cultures were made of fibroblasts from the hearts of chick embryos from 10 to 11 days old. The culture medium was one drop of fowl plasma and one of chick embryo extract. It contained from 200 to 300 I.U. vitamin A per 100 ml. Duplicate halves of the culture were maintained in the medium with and without reinforcement

up to 2000 I.U. per ml. The cultures were maintained for up to 7 days with transfer to fresh medium every 2 days. Preparations were fixed and stained after 2, 4, 5, 6 and 7 days. Cell counts were made of about 500 cells in comparable fields, and the number of mitoses was expressed as a percentage of resting cells.

For the first 4 days the cultures showed no difference. On the fifth day the cell density was greater in the cultures with added vitamin A, and the difference increased for the next 2 days. The progress of mitosis was comparable. In the cultures with added vitamin A, the total number of cell divisions was greater on the fifth day, and by the seventh day the mitotic rate had increased by 50 per cent. and the mitotic count was doubled. The increased cell density was thus due to increased cell division and not only to cell migration. It is recognised that the cultures without added vitamin A might have been inhibited by insufficiency of the vitamin.—E. M. Hume.

320

COHEN, J., MADDOCK, C. L. and WOLBACH, S. B. **The effect of parathyroidectomy on the evolution of hypervitaminosis A in rats: histological and chemical observations.** *Arch. Pathol.*, 1955, **59,** 723–726. [Labs. Nutrit. Res., Child. Med. Centre, Boston, Mass.]

The administration to parathyroidectomised rats of daily doses of 1000 I.U. vitamin A per g. bodyweight caused the same signs of vitamin A excess, including haemorrhage and bone abnormalities, as occurred in intact animals. The injuries caused by vitamin A excess cannot, therefore, be explained by stimulation of the parathyroid gland. In parathyroidectomised animals calcium in the blood was reduced and phosphorus raised, irrespective of the vitamin A intake. With excess of vitamin A proteins were reduced and mucoproteins much increased in both groups.

T. Moore.

PATEL, H. S. and PATEL, B. M. **Loss of vitamin A potency during the preparation of ghee from milk.** *Indian J. Dairy Sci.*, 1955, **8,** 53–60. [Inst. Agric., Anand.]

Carotene and vitamin A were estimated in milk from Kankrej cows and in ghee prepared from the same milk by the direct cream method. Fourteen samples showed an average value for carotene of 2·55 μg. per g. milk fat and 1·96 μg. per g. ghee fat, and for vitamin A of 29 and 20 I.U. per g. fat, respectively. Average percentage loss in the preparation of ghee was 22·4 $\pm$ 3·9 for carotene and 29·7 $\pm$ 4·8 for vitamin A. When colostrum, with higher initial concentrations of carotene and vitamin A, was used for the preparation of ghee the percentage loss was greater, amounting on the average to 25·1 for carotene and 35·9 for vitamin A. Other methods of preparation were shown to have no significant effect on the loss of carotene and vitamin A. When ghee was prepared from buffalo milk by the customary method 10 samples showed an average percentage loss of vitamin A of 19·7 $\pm$ 2·66.—I. M. Sharman.

322

REID, B. L., DAUGHERTY, H. K. and COUCH, J. R. **The stability of vitamin A in mixed feeds and premixes.** *Poultry Sci.*, 1955, **34,** 603–608. [Dept. Poultry Husb., Texas Agric. Exp. Stat., College Station.]

A stabilised concentrate of vitamin A or a fortified fish liver oil, each containing 10,000 I.U. vitamin A per g., was added to mixed rations otherwise free from vitamin A or provitamin. The diets included a chick starter, turkey starter, beef cattle supplement, supplement for pigs containing 15 per cent. protein, commercial milk replacer and a commercial brand of dog biscuit. The supplements were added to give 10,000 I.U. vitamin A per lb. feed. The fortified rations were then stored for 4 months in amounts ranging from 5 to 100 lb. in a warehouse with little ventilation where the temperature varied from 66° to 96° F. Small samples were stored also at 42° F. Vitamin A in each of the fortified diets was estimated after 1, 2, 3 and 4 months' storage. After 4 months' storage the amount of vitamin A, added as the stabilised concentrate, which remained in the feeds and premixes generally ranged from 87 to 98 per cent. of that originally added. There was an unexplained fall in the vitamin A content of the chick starter, which dropped to only 27 per cent. Loss of vitamin A from the diets fortified with the fish liver oil was much more rapid at all stages, and after 4 months the content was only from 2 to 51 per cent. of the initial value. Loss of vitamin A was retarded in the samples stored at 42° F., and in the diets fortified with fish liver oil the amount retained was about 1½ times that in the corresponding samples stored in the warehouse.

Biological tests with chicks gave results in good agreement with those of the chemical estimation. Three groups of chicks given the feed containing the stabilised concentrate stored for 1, 2 or 3 months remained healthy during a 10-week period; the average content of vitamin A in the liver of the chicks at the end of the period was 24·8, 22·3 and 26·3 I.U. per g., respectively.—I. M. Sharman.

323

OLSSON, N., ÅKERBERG, E. and BLIXT, B. **Investigations concerning formation, preservation and utilization of carotene.** *Acta Agric. scand.*, 1955, **5,** 113–184.

In 1941 several members of the Scandinavian Agricultural Research Workers' Association collaborated in 4 countries in the investigation of carotene problems. Their researches were published from time to time. This article in English summarises them ; many of the reports have already been abstracted.

The paper gives tables of carotene content for different parts of grasses, oats, clovers, lupins, vetches, peas and carrots (Absts. 1657, 1660, Vol. 17 ; 3296, Vol. 20), and describes studies on the effect of climate and the relation between stage of development and carotene content in leafy plants and carrots (Abst. 2846, Vol. 16) ; the effect of light on carotene formation in growing clover ; the correlation of carotene with protein and with fibre ; the correlation of carotene with other pigments ; polyploidy in clovers ; the stability of carotene in stored carrots, green silages and dried forage crops (Absts. 4025, 4078, Vol. 16) ; and the utilisation of carotene by man (Abst. 2466, Vol. 17), pigs (Absts. 2828, 3060, Vol. 16), cows (Absts. 2844, Vol. 16 ; 2933, Vol. 24) and laying hens (Abst. 2825, Vol. 23).—V. H. Booth.

BALASUNDARAM, S., CAMA, H. R., SUNDARESAN, P. R. and VARMA, T. N. R. **High-potency vitamin A_2 oils from Indian freshwater fish.** *Nature*, 1955, **176**, 554. [Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

The content of vitamin A_1 and A_2 in the liver oils of Indian freshwater fish was estimated spectroscopically and by the $SbCl_3$ colour reaction. In each of the species investigated, *Callichrous bimaculatus*, *Ophiocephalus straitus* and *Wallago attu*, vitamin A_2 exceeded by about 9 times the amount of vitamin A_1. The $E\,\frac{1\ \text{per cent.}}{1\ \text{cm.}}$ values at 351 mμ. for vitamin A_2, and at 325 mμ. for vitamin A_1, in the three species, were 211 and 26, 200 and 25, and 106 and 11, respectively. The oils were further investigated by a chromatographic technique with 5 per cent. weakened alumina, which showed that most of the vitamin A_2 in the oil was in the ester form. Vitamin A_1 ester was not present, only the alcohol form being found. A small quantity of vitamin A_2 alcohol was present in each of the oils.—I. M. Sharman.

VITAMIN D

325

TSCHAPKE, H. and PLESSING, H. Chemische Vitamin D-Bestimmung mit Zinn (II)-chlorid. [**Chemical estimation of vitamin D with stannous chloride.**] *Naturwissenschaften*, 1955, **42**, 417. [Anst. Vitaminforsch. Vitaminprüfung, Potsdam-Rehbrücke.]

Several metal halides were tested as reagents for vitamin D, and stannous chloride was found satisfactory. Dissolved in acetyl chloride it gave a yellow colour with pure solutions in chloroform of vitamin D_2 or D_3. With irradiated products it gave a red colour. Vitamin A gave a blue colour which interfered, and the vitamin had to be removed by chromatography. Cholesterol, 7-dehydrocholesterol and ergosterol did not interfere so that the costly and time-consuming precipitation with digitonin could be omitted. The method is described in detail. The results were read in a Pulfrich photometer with filter S50. A curve of reference was constructed with pure vitamin D_2. Examples are given showing the close correspondence of the results obtained by the method and biologically for an assortment of materials.

E. M. Hume.

326

MARIANI, A. and CAVINA, G. Determinazione di vitamina D_2 in presenza di vitamina A in prodotti farmaceutici ed in concentrati naturali. [**Estimation of vitamin D_2 in presence of vitamin A in pharmaceutical preparations and natural concentrates.**] *Rend. Ist. Super. Sanità, Rome*, 1955, **18**, 232–237. [Lab. Biol., Ist. Super. Sanità, Rome.] French, English and German summaries.

In the method previously described (*Rend. Ist. Super. Sanità, Rome*, 1953, **16**, 725), vitamin A was selectively destroyed by chromatography in benzene solution on bentonite, but a small amount of a destruction product passed through the column and interfered with the spectrophotometric estimation of vitamin D_2 after reaction with $SbCl_3$. It was found that the water content of the bentonite adsorbent greatly affected the amount of the destruction product passing through the column. Superfiltrol, washed with benzene and dried at 40° C. with exactly 4 per cent. of water added, was found satisfactory. Results of applying the method to mixtures of vitamin A and vitamin D in pure solution and in pharmaceutical products are tabulated.—E. M. Hume.

FESTENSTEIN, G. N., HEATON, F. W., LOWE, J. S. and MORTON, R. A. **A constituent of the unsaponifiable portion of animal tissue lipids ($\lambda_{max.}$ 272 mμ.).** *Biochem. J.*, 1955, **59**, 558–566. [Dept. Biochem., Univ. Liverpool.]

The presence in the intestine of the horse and pig of an unsaponifiable substance with an ultraviolet absorption maximum at 272 mμ. was described by Festenstein and Morton (Abst. 4804, Vol. 25). In the present study the substance was found also in horse stomach and in the liver, kidney, intestine and submaxillary glands of normal rats and of rats deprived of vitamin A. It was not found in ox or sheep intestine or in the bladder, testis or vagina of rats deprived of vitamin A. From its polarity, infrared and ultraviolet absorption, and probable empirical formula of $C_{28}H_{42}O_2$, it was considered that the substance might be a steroid containing the chromophoric grouping 8(9)-ene-7 : 11-dione.—D. Duncan.

TALMAGE, R. V. and DODDS, B. F. **Comparative study of some effects of administration of dihydrotachysterol and calciferol to rats.** *Endocrinology*, 1955, **57**, 236–242. [Dept. Biol., Rice Inst., Houston, Tex.]

Ca and P were estimated in the blood and urine of about 190 male rats weighing between 175 and 250 g., maintained on a standard Purina diet or on a Ca-free diet. Some were injected intraperitoneally with 5 μC. ^{32}P. Calciferol in propylene glycol and dihydrotachysterol in sesame oil were given orally.

In the 72 hr. during which 200 μg. dihydrotachysterol was given daily, urinary and serum Ca on the normal or Ca-free diet increased more with dihydrotachysterol than without it ; serum and urinary P increased at first, but not progressively.

In a similar experiment with parathyroidectomised rats, given 200 μg. dihydrotachysterol daily for 1 or 2 days before the operation, urinary excretion of ^{32}P increased within a few hours after operation to normal or over, though it was greatly reduced when dihydrotachysterol was not given or was given only at the same time as the operation. Serum inorganic P rose somewhat but not greatly in all the rats subjected to parathyroidectomy. Serum Ca was prevented from falling after the operation when dihydrotachysterol had been given beforehand. Urine Ca rose in all the animals after operation, most in those given dihydrotachysterol for 2 days beforehand. The experiment was repeated with rats given 400 μg. dihydrotachysterol or the same amount of vitamin D_2. The vitamin failed to duplicate the action of dihydrotachysterol, the results with it differing little from those for untreated parathyroidectomised animals.

HANSSLER, H. Experimentelle Untersuchungen über den Einfluss des D-Vitamin auf die Funktion von Thymus und Milz. [**Experimental studies on the effect of vitamin D on the function of the thymus gland and spleen.**] *Ztschr. ges. exp. Med.*, 1955, **126**, 105–115. [Kinderklin., Univ. Tübingen.]

The possibility that vitamin D acts on the body through the spleen and thymus gland, by inhibiting their production of a substance which reduces serum Ca and P, as suggested by Nitschke (Abst. 226, Vol. 3), and not through the parathyroid

glands, was investigated. The size of the nuclei in the 2 organs was used to assess their activity, in the same way as was previously done for the parathyroid glands (Absts. 1729, 2954, Vol. 24). The nuclei were measured in the reticular cells of the thymus and in the nodular marginal zone of the spleen, small nuclei being taken as a sign of inactivity. Young rats weighing from 30 to 40 g. were given for from 20 to 40 days diets high or low in Ca, with or without daily amounts of vitamin D_2 or vitamin D_3 ranging from 1 to 40,000 I.U., or with A.T. 10. There was no difference in the size of the nuclei whether the diet was low or high in Ca unless vitamin D was given, although the serum Ca value might be very different. Even with the lowest doses of vitamin D the cell nuclei were significantly smaller than without. The effect of A.T. 10 was the same, but it was less active.

It is concluded that vitamin D acts on the spleen and thymus to lower their activity, and that its effect on those organs is unrelated to the serum Ca value. Further, apart from the spleen and thymus, vitamin D raises the serum Ca value and thereby inactivates the parathyroid glands.—E. M. Hume.

ENGFELDT, B. and ZETTERSTRÖM, R. **Biophysical studies of the bone tissue of dogs with experimental rickets.** *Arch. Pathol.*, 1955, **59,** 321–331. [Dept. Physical Cell Res., Karolinska Inst., Stockholm.]

Of 3 dogs 2½ months old, 2 were fed on a rachitogenic diet and kept in darkness until, after a month, they had developed rachitic changes, mild as seen radiographically. All 3 were then given an intravenous injection of 1 mC. $Na_2H^{32}PO_4$ and were killed 3 hr. later. Thin longitudinal sections were cut of the epiphyses and metaphyses of the long bones. Some bones were first decalcified. The distribution of mineral salts in the section was determined by microradiography and radio-autography. The exchangeability of the Ca ions in the bone minerals was investigated by incubating bone sections, in which the radio-activity had faded, in $^{45}CaCl_2$ solution and making radio-autograms. The ultrastructure of the bone tissue was investigated by X-ray diffraction. The appearance of the sections is illustrated and described.

In rickets, mineralisation of the newly formed organic matrix, though arrested, was not wholly lacking. There was a thin zone of higher X-ray absorption at the outer border of the osteoid tissue; apatite was present, and there was uptake of ^{45}Ca *in vitro* in the same zone. In polarised light the orientation of the collagen fibres was disturbed, so that it was clear that the development of the organic matrix was abnormal as well as its mineralisation.—E. M. Hume.

HERZFELD, E., KLUPP, H., LOUDON, M. and ZWEYMÜLLER, E. Beitrag zur experimentellen Vitamin D-Vergiftung beim Hund. 1. Die Wirkung von Vitamin D_2 auf die maximale tubuläre Rückresorption von Phosphat (*Tm* PO_4) bei osmotischer Diurese und normaler Glomerulusfiltrationsgrösse. [**Experimental vitamin D intoxication in the dog. 1. The effect of vitamin D_2 on maximum tubular reabsorption of phosphate (*Tm* PO_4) in osmotic diuresis and normal glomerular filtration.**] *Ztschr. ges. exp. Med.*, 1955, **126,** 33–39. [Inst. Pharmakol., Univ. Vienna.]

Seven healthy adult female dogs, weighing from 10 to 24 kg., were transfused with a mixture of primary and secondary Na phosphate. The solution was hypertonic to promote diuresis and contained inulin for estimation of the glomerular filtration rate. Inulin and inorganic P were estimated in the blood and urine, and the method of calculating the tubular re-absorption of P from the data is set out. Several tests were made without vitamin D, which was then given as a single oral dose of 1 mg. vitamin D_2 per kg. bodyweight in oil solution, and tests were made 1, 2, 5 and 12 days later; in all, 32 such clearance tests were made. In none of the tests after administration of vitamin D was there any change in the tubular re-absorption rate outside the normal range of variation. There was no change in the concentration of residual N in the blood, showing that there had been no toxic action of vitamin D.

RÄIHÄ, C. E. and FORSANDER, O. **Vitamin D and phosphorylation of thiamin.** *Acta paediat.*, 1954, **43,** Suppl. 100, 541–544. [Child. Clin., Univ. Helsinki.]

Three groups of from 2 to 5 rats were maintained on a diet deficient in vitamin D, one group receiving in addition 1000 I.U. vitamin D every 7 days. After 19 days the last group and a second group received 1000 I.U. vitamin D and 10 mg. vitamin B_1. The third group received only 10 mg. vitamin B_1. The supplements were mixed in the food. Two days later the heart blood was taken and cocarboxylase was estimated in it by the method of Westenbrink *et al.* (Abst. 1288, Vol. 15). The mean value for cocarboxylase in the group given vitamin D throughout was 13·2, for the group given vitamin D only at the same time as vitamin B_1 11·0, and for the group given vitamin B_1 and not given vitamin D at all 9·4. [The values are stated as per 100 ml. blood but no unit is given; presumably it should be μg.] The second and third group had signs of rickets.

The experiment was repeated with somewhat different amounts of vitamin D and with vitamin

B_1 given by injection instead of in the food. The corresponding values were 13·2, 13·0 and 9·3.

HORN, V. and EDER, H. Zur Frage der Beeinflussung der D_2-Wirkung bei Küken durch Antibiotika. [**Problem of modifying the effect of (vitamin) D_2 on chickens with antibiotics.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 65–67. [Vet. Physiol. Inst., Justus Liebig Hochsch., Giessen.]

One hundred day-old Leghorn cockerels were given a diet on which rickets had been found to develop in from 4 to 5 weeks. After one week on the diet alone, 7 groups received daily 0·025 μg. vitamin D_3, or 0·25 or 0·5 μg. vitamin D_2, or the same 2 doses of vitamin D_2 with penicillin, or no addition. Penicillin was added as 25 mg. Procain-penicillin Bayer per kg. food. At the age of 5 weeks the tarsal-metatarsal distance was measured in X-ray photographs of the foot. Only the chicks receiving vitamin D_3 were protected against rickets. Penicillin appeared to have no effect on the activity of vitamin D_2.—E. M. Hume.

MEINTZER, R. B. and STEENBOCK, H. **Vitamin D and magnesium absorption.** *J. Nutrition*, 1955, **56,** 285–294. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Rats weighing about 90 g. were maintained in metabolism cages, and Mg balance experiments were made lasting 3 days. The diet was low in P, Ca and Mg, the respective percentages being 0·016, 0·012 and 0·02; it contained, per cent., Cerelose 67, cooked egg white 18, roughage 3, cottonseed oil 10 and salts, not including Ca, P or Mg, 2. Vitamins were added except vitamin D, which, when given, was administered as 75 I.U. vitamin D_2 per 3-day period. Additions were made to the diet of Mg phosphate, Mg carbonate, and Mg phytate in an acidic and a basic form, and sometimes also of 1 per cent. of $CaCO_3$.

In 12 experiments with 170 rats, administration of vitamin D always increased the absorption of Mg by an amount never exceeding 19 per cent. but, through loss in the urine, the retention was actually diminished. Mg was absorbed readily even when given as phosphate or phytate or in presence of excess base with added $CaCO_3$ and $NaHCO_3$. Retention of Mg was highest when phosphate intake was high, 0·34 per cent. of the diet. In 4 out of 5 experiments there was an increase in P retention when vitamin D was given. Phytic acid given as Mg phytate was available as a source of P even when vitamin D was not given, and when the extent to which the phytate was hydrolysed was low owing to an increased intake of $CaCO_3$. When additional $CaCO_3$ was not given only a little more phytate was hydrolysed with vitamin D than without it.—E. M. Hume.

SCHEER, K. Tierexperimentelle Untersuchungen über antirachitische Wirksamkeit handelsüblicher uv-bestrahlter Milch. Stellungnahme zu dieser Arbeit von W. Theopold und I. Schulte-Nickell in Monatsschrift für Kinderheilkunde, **102,** H. 5, 262 ff., 1954. [**Animal experiments on the antirachitic value of commercial milk irradiated with ultraviolet light. Comment on the article with this title by W. Theopold and I. Schulte-Nickell, *Monatsschr. Kinderheilk.*, 1954, 102, 262.**] *Monatsschr. Kinderheilk.*, 1955, **103,** 200–203. [Frankfurt a.M.]

The X-ray pictures of 160 rats used by Theopold and Schulte-Nickell in their test (Abst. 370, Vol. 25), were examined and re-evaluated with the conclusion that the original assessment was too rough and returned too large a proportion of animals as rachitic.

The results are summarised of tests, both published and unpublished, in which good vitamin D potency was found in milk irradiated by the same process as that used in Frankfurt (Coates *et al.*, Abst. 1883, Vol. 25; Engel, Abst. 4813, Vol. 25; Wodsack; Holtz; Czerny Krankenhaus, Univ. Heidelberg).

X-ray photographs are reproduced of 2 babies with florid rickets, cured by administration of milk irradiated by the process used in Frankfurt.

E. M. Hume.

340

THEOPOLD, W. Schlusswort zu den Bemerkungen von Herrn. Professor Scheer. [**Final comment on the remarks of Professor Scheer.**] *Monatsschr. Kinderheilk.*, 1955, **103,** 203–205. [Kinderklin., Univ. Marburg a.d. Lahn.]

Photographs are reproduced of sections of the bones of rats used in the test criticised by Scheer (preceding Abst.), showing the presence of gross rickets. The cure of rickets in the 2 babies is criticised as having occurred in April and May.

EGGITT, P. W. R. and WARD, L. D. **The chemical estimation of vitamin-E activity in cereal products. 2. Millers' offals and compound animal foods.** *J. Sci. Food Agric.*, 1955, **6**, 329–337. [Dept. Appl. Biochem., Univ. Birmingham.]

For Part 1 see Abst. 2965, Vol. 24. The tocopherol pattern was estimated by the method described in Part 1 in fine wheat feed, coarse bran, commercial and purified wheat germ meal and 2 poultry feeds. The method was modified for the poultry feeds by doubling the quantity of pyrogallol and alkali used in the saponification. Coarse bran contained 6·5 mg. tocopherols per 100 g. and, by elution of the spots on paper chromatograms, was shown to contain 9 per cent. in the "origin spot", 9 per cent. α-tocopherol, 15 per cent. β-tocopherol and 67 per cent. ε-tocopherol. The values for fine wheat feed were 8·1 mg. per 100 g. and 13, 23, 21 and 43 per cent. of the respective tocopherols. Commercial wheat germ meal contained 26 mg. total tocopherols per 100 g. and had 14 per cent. origin spot, 49 per cent. α-tocopherol, 28 per cent. β-tocopherol and 9 per cent. ε-tocopherol, compared with 27 mg. per 100 g. and 14, 54, 29 and 3 per cent. of the respective tocopherols for purified wheat germ in which the coarse bran fragments had been removed by hand picking. Of the balanced poultry feeds, chick mash contained 5·6 and breeder mash 5·0 mg. total tocopherols per 100 g. with 19 and 20·5 per cent. origin spot, 22 and 16 per cent. α-tocopherol, 35 and 33 per cent. β- plus γ-tocopherol and 24 and 30·5 per cent. ε-tocopherol, respectively. The 2 mashes had a calculated vitamin E potency of 1·8 and 1·3 mg. per 100 g.—R. J. Ward.

SCOTT, M. L., HILL, F. W., NORRIS, L. C., DOBSON, D. C. and NELSON, T. S. **Studies on vitamin E in poultry nutrition.** *J. Nutrition*, 1955, **56**, 387–402. [Dept. Poultry Husb., Cornell Univ., Ithaca, N.Y.]

Male chicks were given a basal diet deficient in vitamin E, composed of torula yeast, glucose, vitamin-E-free lard and ground cellophane with added amino-acids, minerals and vitamins. The basal diet was given alone or with supplements of α-tocopheryl acetate, γ-tocopherol, diphenyl-*p*-phenylenediamine, butylated hydroxyanisole, nordihydroguaiaretic acid, 2 : 5-di-*tert.*amylhydroquinone, 6-ethoxy-1-2 :-dihydro-2 : 2 : 4-trimethylquinone, crude lecithin or purified phosphatides. With all the supplements the incidence of exudative diathesis was 100 per cent. and all the birds died by the 5th week except those receiving γ-tocopherol, which delayed the onset of exudative diathesis and death, and α-tocopheryl acetate, which gave complete protection.

In a second experiment chicks were given the basal diet with and without supplements of α-tocopheryl acetate, dried brewer's yeast or diphenyl-*p*-phenylenediamine, or a combination of the first and second, or of the second and third, supplements. Complete protection was given by α-tocopheryl acetate and dried brewer's yeast.

A third experiment showed that the vitamin-E-like activity of the dried brewer's yeast was in the fraction insoluble in hexane, and was thus not fat-soluble. Chicks receiving the basal diet showed microcytic anaemia.

In a fourth experiment the basal diet was altered by reducing the content of protein. The chicks had poor growth, severe exudative diathesis, leg weakness and gizzard erosion. Addition of methionine improved growth and alleviated gizzard erosion but did not affect exudative diathesis or leg weakness. Addition of vitamin E as well as methionine greatly increased growth and prevented all disorders.

For a fifth experiment cod liver oil was used instead of lard in the basal diet. Dried brewer's yeast or vitamin E again prevented exudative diathesis and leg weakness, but cystine improved only gizzard erosion and growth.—R. J. Ward.

VELLING, G. Ernaeringslidelse hos aellinger og kyllinger, formentlig fremkaldt af mangel på vitamin E. [**Nutritional disease in ducklings and chicks probably produced by lack of vitamin E.**] *Nord. Vet.-Med.*, 1955, **7**, 573–588. [Lab. Fjerkraeundersøgelser.] French, English and German summaries.

Literature is reviewed. During the years 1953 and 1954, out of 337 ducks sent for examination to the Poultry Research Laboratory, 22 had muscular dystrophy. In some paralysis developed slowly; in others it was rapid and almost immediately fatal. Of those recorded as sick, from 25 to 30 per cent. died.

The pathological findings were of individual muscles or groups of muscles of light colour with a "boiled" look; gizzard muscle might be severely affected. Histologically there was hyaline

necrosis, fragmentation, and cellular infiltration in the connective tissue round necrotic fibres. Sometimes there were calcareous deposits.

In the autumn of 1954 there was an epidemic of "crazy chick" disease with the characteristic signs; 80 certain specimens and 50 doubtful were received in a total of 6062. Chicks, only from 3 to 5 weeks old, were chiefly attacked; percentage mortality in affected flocks was usually from 1 to 5 but in some was as high as 10. Pathological and histological findings were of the characteristic oedema, necrosis, haemorrhages and hyaline thrombi in the capillaries of the cerebellum.

Inquiries and interviews on affected holdings suggested that too much cod liver oil was given on many farms. It is difficult to mix cod liver oil uniformly in a ration and unequal dispersal might explain the uneven incidence of the disorder. Empirical treatment by reduction of the protein part of the ration with corresponding increase of grain and omission of cod liver oil caused the recovery of all but those most severely affected. After experimental administration of a vitamin E preparation to a small number of crazy chicks some recovered, but the recovery may have been due to a simultaneous change of diet.—I. Leitch.

IRVING, J. T. and BUDTZ-OLSEN, O. E. **The relation between the action of vitamin E and protein in the body, and the influence of various fish-liver oils in the diet upon vitamin E activity in vivo.** *Brit. J. Nutrition*, 1955, **9**, 301–309. [Joint Dent. Res. Unit, Counc. Sci. Indust. Res. and Univ. Witwatersrand, Johannesburg.]

Young rats of 50 g. weight were given a diet deficient in vitamin E and low in protein, composed of potato starch, dried brewer's yeast and fish liver oil. The percentage of fish liver oil, which was cod or hake, was 20, 10 or 2·5, with corresponding adjustments made in the potato starch content. α-Tocopheryl acetate, 3 mg. daily, was given to some rats.

On the diets with hake or cod liver oil the animals lost weight or made very small gains. Vitamin E improved the weight gain of the rats having cod liver oil but had hardly any effect on those given hake liver oil. When the protein content was raised from 9·3 to 18·8 per cent. by substitution of egg albumin for 12·5 per cent. of the potato starch, the rats having both oils gained weight, but those with hake liver oil gained more slowly.

The incisor teeth of the rats having the cod liver oil diet were all white after 30 days, and the enamel organ was consistently affected after 20 days. Tocopherol completely protected the enamel organ and the colour of the teeth. Extra protein gave protection to the enamel organ but the teeth turned white.

Similar results were obtained with the rats having hake liver oil, but tocopherol gave no protection, and the degree of protection by extra protein was not as good as with cod liver oil. Extra protein and tocopherol together gave complete protection.

The dialuric acid haemolysis test was positive in all the rats receiving no tocopherol except in those having hake liver oil with extra protein. No pathological change was found in the kidneys of the rats having hake liver oil or the smaller amounts of cod liver oil. Degeneration of the convoluted tubules was found in the kidneys of the rats with 20 per cent. cod liver oil in the diet.

ROSENKRANTZ, H. **Studies in vitamin E deficiency. 1. The oxygen consumption of various tissues from the rabbit.** *J. Biol. Chem.*, 1955, **214**, 789–797. [Worcester Found. Exp. Biol., Shrewsbury, Mass.]

Young rabbits weighing from 600 to 1200 g. were given a diet deficient in vitamin E and were kept in glass metabolism cages. Creatine and creatinine were estimated daily in the urine. Loss of appetite, decline in weight and muscular paralysis occurred in about 3 weeks. In order to estimate oxygen consumption of the tissues before irreversible biochemical or physiological changes might have occurred, the animals were killed when the urinary creatine output was below 20 mg. in 24 hr. Oxygen uptake was measured in slices and strips of skeletal muscle, bisected adrenal glands and kidney, liver and heart slices with and without calcium in the medium. In the deprived animals compared with non-deprived the oxygen uptake by slices of skeletal muscle was increased by 48 per cent. and of muscle strips by 54 per cent. in presence of Ca but there was little or no change in the absence of Ca; the increase in the oxygen uptake of the adrenal glands was 71 per cent. and of the liver 65 per cent. in presence of Ca, and 104 and 91 per cent., respectively, in absence of Ca. No change was found in the kidneys and heart. The increase in oxygen uptake of the adrenal glands was in the cortex; a similar increase was found in rabbits on a diet deficient in vitamins A and D, in pregnant rabbits on a stock diet, and in a rabbit with a broken leg.—R. J. Ward.

348

HOVE, E. L. and SEIBOLD, H. R. **Liver necrosis and altered fat composition in vitamin**

E-deficient swine. *J. Nutrition*, 1955, **56**, 173–186. [Dept. Animal Husb., Agric. Exp. Stat., Auburn, Ala.]

Six pigs were fed from weaning on a diet deficient in vitamin E and containing 2 per cent. cod liver oil and only 6 per cent. protein. Three of them died suddenly and were found to have massive acute haemorrhagic necrosis of the liver. Histological examination of the liver of the 3 survivors showed post-necrotic cirrhosis in 2 of them. The percentage of fat in the liver was 1·56 compared with 2·31 in pigs given vitamin E. Estimation of linoleic, arachidonic and pentaenoic acids in the muscle fat showed an average percentage of 3·09, 1·36 and 0·72, respectively, for the deprived pigs and 5·37, 2·19 and 1·14 for those given vitamin E. Liver fat showed a higher value for arachidonic acid, 6·54 per cent., for the deprived pigs than that, 5·78 per cent., for the non-deprived, but the concentration of linoleic and pentaenoic acids was lower in the deficient animals. Maize contains only small amounts of vitamin E, about 6 mg. α-tocopherol per kg., so it is probable that pigs given a diet based on maize and including cod liver oil, and without access to pasture or other source of vitamin E, will develop the fatal liver necrosis described.—I. M. Sharman.

349

WEINSTOCK, I. M., SHOICHET, I., GOLDRICH, A. D. and MILHORAT, A. T. **The effect of vitamin E deficiency on the oxidation of tricarboxylic acid cycle intermediates.** *Arch. Biochem. Biophys.*, 1955, **57**, 496–505. [Dept. Psychiat., Cornell Univ. Med. Coll., New York.]

Young rabbits were kept on a diet deficient in vitamin E, with or without a supplement of *dl*-α-tocopherol. After from 4 to 5 weeks they were killed, and systems were set up containing washed liver homogenate, cytochrome *c*, adenosine triphosphate and an intermediate of the tricarboxylic acid cycle. With α-ketoglutarate, succinate, fumarate, L-malate and oxalacetate the rate of oxygen uptake was from 60 to 600 per cent. higher for the liver of deprived than of non-deprived animals. With citrate, the slight increase in activity was not statistically significant. The addition of fluoride to the systems only slightly reduced the excessive oxygen uptake of the deficient tissues. The replacement of adenosine triphosphate by the diphosphate or monophosphate eliminated the difference in oxygen uptake between the deprived and non-deprived livers by increasing the uptake of the latter.—T. Moore.

DI BELLA, S. Inibizione della glicolisi anossibiontica del midollo osseo determinata da α-tocoferolo. [**Inhibition of anaerobic glycolysis in the bone marrow by α-tocopherol.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 1035–1037. [Ist. Chim. Biol., Univ. Sassari.]

The extent of anaerobic glycolysis by homogenates of bone marrow, expressed as μg. lactic acid per g. fresh bone marrow, was on average 44·7 per cent. less for 6 rats maintained for a month on an adequate diet with addition of 3 mg. α-tocopherol [presumably daily] than for 6 rats having the same diet without added tocopherol. For the same 2 groups of rats the aldolase activity of the bone marrow was on the average 52·8 per cent. less in the rats given added tocopherol.

NASON, A., and LEHMAN, I. R. **Tocopherol as an activator of cytochrome *c* reductase.** *Science*, 1955, **122**, 19–22. [McCollum-Pratt Inst., Johns Hopkins Univ., Baltimore, Md.]

Cytochrome *c* reductase was prepared from normal muscle by a procedure involving homogenisation, dialysis and fractional centrifuging. The addition of α-tocopherol in a suspension of ethanol-globulin or -albumin to a system containing cytochrome *c*, diphosphopyridine nucleotide and the enzyme matured by storage at — 15° C. caused an increase in activity of up to sixfold. With the fresh enzyme high activity was observed even without tocopherol, which suggested that a substance having the same activity as tocopherol must be loosely attached and lost during storage. In agreement with the view, the activity of the fresh enzyme preparation was reduced by extraction with *iso*octane. α-Tocopheroxide also activated the system, but no activity was shown by numerous other substances tested, including esters of tocopherol, vitamin K_1, vitamin D_2, cholesterol, cystine, lipoic acid, oleic acid and anti-oxidants.

YOUNG, J. M. (Jr.), DINNING, J. S. and DAY, P. L. **Metabolic interrelationships of vitamins E and B_6.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 216–217. [Dept. Biochem., Univ. Arkansas Sch. Med., Little Rock.]

Weanling rats were given a basal diet deficient in vitamins E and B_6 with or without a supplement of one or both vitamins. Bodyweight and food intake were recorded and urine was analysed for creatine, creatinine and allantoin. Xanthurenic acid was estimated in the urine before and after intraperitoneal injection of 50 mg. DL-tryptophan per kg. bodyweight. The inclusion of vitamin B_6 increased growth but vitamin E had no effect. Both vitamins decreased the daily excretion of creatine and allantoin. Vitamin B_6 decreased the excretion of xanthurenic acid after injection of tryptophan; vitamin E had no effect.

MARTIUS, C. and NITZ-LITZOW, D. Zum Wirkungsmechanismus des Vitamin K. [**The mode of action of vitamin K.**] *Biochem. Ztschr.*, 1955, **327**, 1–5. [Physiol. Chem. Inst., Univ. Würzburg.] English summary.

The effect was studied *in vitro* of a number of anticoagulant substances on oxidative phosphorylation in mitochondria from the liver of rats and of chicks reared on a diet lacking vitamin K. Inhibition of phosphorylation was closely related to anticoagulant activity. In tests with vitamin K_1 and two naphthoquinone derivatives with side chains differing in length, the number of C atoms in the side chain seemed to determine the effect on phosphorylation. The experiments are considered as evidence for regarding 2-methyl-1 : 4-naphthoquinone as provitamin K.—A. M. Copping.

YACOWITZ, H., ROSS, E., SANGER, V. L., MOORE, E. N. and CARTER, R. D. **Hemorrhagic syndrome in chicks fed normal rations supplemented with sulfaquinoxaline.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 1–7. [Dept. Poultry Sci., Ohio Agric. Exp. Stat., Wooster.]

When chicks were given a starter ration containing 5 per cent. alfalfa and 5 mg. menadione per lb. and supplemented with 0·1 per cent. sulphaquinoxaline, a haemorrhagic state like one observed in the field appeared in about 25 per cent. of the birds. Procaine penicillin, 2 mg. per lb. feed, greatly increased the incidence of haemorrhages and reduced the haematocrit values. The toxic effect of sulphaquinoxaline was variable. When it was given at 3, 4 or 5 weeks of age, the haematocrit values, measured at 7 weeks of age, were reduced, but in chicks given the drug at 2 days old the haematocrit values were almost normal. Some chicks were more resistant than others. The incidence of haemorrhages was higher in chicks on a broiler ration than in those on the starter mash, which is ascribed to the more rapid growth on the broiler ration. When 0·5 g. iodinated casein was included per lb. ration to introduce a stress factor the incidence and severity of the haemorrhages were increased.—E. M. Cruickshank.

CIANCIMINO, C. Comportamento dei lipidi epatici in seguito a somministrazione di vitamina K nei ratti alimentati con dieta steatogena. [**Behaviour of liver lipids after administration of vitamin K in rats fed on a diet to produce fatty liver.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 912–913. [Ist. Fisiol., Univ. Palermo.]

Two groups of adult male rats were fed for 25 days on a diet containing, per cent., sucrose 50, beef fat 40, casein 5, agar 1 and salts 4, with added vitamins not including vitamin K. One group received 1 mg. vitamin K per head daily by mouth. In the liver, total lipids, fatty acids and unsaponifiable fraction were estimated. The means and ranges for all 3 values were considerably higher in the rats given vitamin K.—E. M. Hume.

VITAMIN B COMPLEX: GENERAL

356

GIRI, K. V. and BALAKRISHNAN, S. **Circular paper chromatographic method for estimation of thiamine and riboflavin in multivitamin preparations.** *Anal. Chem.*, 1955, **27**, 1178–1180. [Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

A chromatographic method based on that of Giri and Rao (Abst. 1500, Vol. 22) was evolved for simultaneous estimation of vitamin B_1 and riboflavin on filter paper of 18 or 24 cm. diameter. Vitamin B_1 was converted to thiochrome and both vitamins were measured with a fluorimeter. Standard chromatograms for known concentrations of vitamin B_1 and riboflavin were prepared and reference curves constructed so that the method could be applied to vitamin mixtures. Acetic acid extracts were used and the chromatograms were found to be stable for up to 14 days after preparation.—A. M. Copping.

357

BRUST, M. and FRAENKEL, G. **The nutritional requirements of the larvae of a blowfly, *Phormia regina* (Meig.).** *Physiol. Zoöl.*, 1955, **28**, 186–204. [Dept. Entomol., Univ. Illinois, Urbana.]

Growth of blowfly larvae was investigated with a purified medium. Satisfactory results were obtained with a mixture of casein, cholesterol, McCollum's salt mixture No. 185, all known vitamins of the B complex and agar. Addition of yeast slightly increased the growth rate. Vitamin B_1, riboflavin, nicotinic acid, pyridoxine and pantothenic acid were essential for any growth, and other substances for optimum growth. A caseinate or a

hydrolysate of casein could not replace casein. Cholesterol was more effective than other sterols. The constituents of the medium were similar to those required by other insects, and no specific requirement was found to account for the very rapid growth of blowfly larvae.—A. M. Copping.

358

WESTERMAN, B. D., OLIVER, B. and MACKINTOSH, D. L. **Influence of chilling rate and frozen storage on B-complex vitamin content of pork.** *J. Agric. Food Chem.*, 1955, **3,** 603–605. [Dept. Foods Nutrit., Kansas Agric. Exp. Stat., Kansas State Coll., Manhattan.]

Vitamin B_1 and riboflavin were estimated chemically and pantothenic and nicotinic acid microbiologically in pork loin kept for 1, 3 or 7 days at 30° F. or 7 days at 40° F. before being frozen for storage. Regardless of treatment, it seemed that muscle from animals killed in January contained more vitamin B_1 than from those killed in June. The reverse was true of nicotinic and pantothenic acid. No seasonal change was found in riboflavin content. Loss of vitamin B_1 and riboflavin was greater than of the other B vitamins during storage and was most marked in meat kept 3 days at 30° F. before freezing. The greatest loss of nicotinic and pantothenic acid occurred in pork kept for one day at 30° F. before freezing. Palatability tests showed undesirable flavours in meat stored for 48 weeks, regardless of the rate of chilling and nature of the preliminary handling. Storage beyond 24 weeks produced off-flavour in the fat except in pork loin kept only one day at 30° F. before freezing.—A. M. Copping.

VITAMIN B_1 (ANEURIN, THIAMINE)

359

VILLANUEVA, J. R. **A new method for the microbiological assay of thiamin (vitamin B_1).** *Nature*, 1955, **176,** 465. [Inst. Edafalogia, Consejo Superior Invest. Cient., Madrid.]

The paper is a preliminary note on the use of the fungus *Tuberculina persicina* for estimating vitamin B_1, in the presence of which growth and pigment production were stimulated, and the depth of colour could be used as a measure of the vitamin.—A. M. Copping.

360

HOFF-JØRGENSEN, E. and HANSEN, B. **A microbiological assay of vitamin B_1.** *Acta chem. scand.*, 1955, **9,** 562–566. [Biochem. Inst., Univ. Copenhagen.]

The organism was the yeast *Kloeckera brevis* B768. The medium and the method are described. Vitamin B_1 was estimated by this method and by the thiochrome method in several materials and the results agreed closely. The method makes possible the estimation of 0·001 μg. vitamin B_1 per ml. extract with a standard deviation of less than 10 per cent.—D. Duncan.

361

RANGANATHAN, B. and BHAT, J. V. **Growth response of a marine yeast, *Cryptococcus laurentii*, to thiamine.** *J. Indian Inst. Sci.* [*A*], 1955, **37,** 154–159. [Fermentation Technol. Lab., Indian Inst. Sci., Bangalore 3.]

In an initial series of tests the yeast responded quantitatively to small graded doses of vitamin B_1 in a purified basal medium. In further tests, 5 months later, there was no grading in response to small doses, and repeated investigation showed that the organism had become able to synthesise vitamin B_1. The observation is discussed in relation to inconsistent results obtained with yeasts in microbiological tests.—A. M. Copping.

362

ROSSI-FANELLI, A. and MONDOVI, B. Separazione elettroforetica su carta degli esteri fosforici della tiamina. 2. [**Separation by electrophoresis on paper of the phosphoric esters of vitamin B_1. 2.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 1008–1011. [Ist. Chim. Biol., Univ. Rome.]

For part 1 see Title 4856, Vol. 25.

The rate of electrophoretic migration on paper by vitamin B_1 and its 3 phosphate esters was studied at *p*H from 3·5 to 9. The results are tabulated.—E. M. Hume.

363

UTZINO, S. and YAMAMOTO, T. **On the stability of thiamin solution. 1. Influence of protein bodies and blood plasma on the stability of thiamin or cocarboxylase solution.**

UTZINO, S. and SHIMATANI, M. **2. Influence of amino acids and various salts on the stability of thiamin in neutral or alkaline solution.** *Acta Scholae med. Univ. Kioto*, 1955, **32,** 97–101; 102–111. [Dept. Med. Chem., Fac. Med., Univ. Kyoto.]

1. Solutions of vitamin B_1 kept at 20° C. for 5 hr. were stable at *p*H values of from 3·5 to 5·5, but at higher values and especially at 6·7 or above the stability declined rapidly. Rabbit blood cells or plasma improved the stability of both vitamin B_1 and cocarboxylase at *p*H 7; cells and plasma

were equally effective for 3 hr., but after 24 hr. only plasma remained effective. Casein, globulin, gelatine and peptone all stabilised vitamin B_1 solutions for 3 hr. at *p*H 8, but glucose, creatine or ascorbic acid did not. Cu, Fe and Mn ions appeared to accelerate decomposition of vitamin B_1.

2. Glycylleucine, leucylglycine, diglycine, triglycine, alanine, glycine, benzoyldiglycine, benzoylglycine, acetylglycine, tyrosine, tyramine, taurine, citrate, phosphate, borate, tartrate and carbonate all increased the stability of vitamin B_1. Sulphanilic acid, sulphanilamide, urea, creatine, glycine anhydride, sodium acetate, Na_2SO_3, $Na_2S_2O_3$, NaCl, Na_2SO_4 and KNO_3 had no value. When vitamin B_1 solution was partly decomposed after 40 min. at *p*H 7·0 or 8·0, addition of cysteine partly restored the thiochrome reaction.—D. Duncan.

364

TAMAKI, T. and NOSE, Y. **Determination of allithiamine.** *J. Vitaminol., Japan*, 1954, **1,** No. 2, 1–5. [Biochem. Inst., Kyoto Prefectural Univ., Nishijin, Kyoto.]

Allithiamine was estimated by adding a citrate and phosphate buffer and cysteine to extracts before application of the thiochrome method. In blood, allithiamine and vitamin B_1 propyl disulphide were rapidly converted into vitamin B_1. Vitamin B_1 disulphide appeared to be an intermediary product in the conversion.—A. M. Copping.

365

WORDEN, A. N., WATERHOUSE, C. E. and PARTINGTON, H. **The response of the dog to test doses of vitamin B_1 hydrochloride.** *Vet. Rec.*, 1955, **67,** 503–509. [Cromwell House, Huntingdon.]

For previous work see Abst. 4400, Vol. 24.

The same 3 dogs, differing in breed, sex and weight, were used and they had a standard diet of known vitamin B_1 and riboflavin content and a standard water intake. Excretion in the urine of vitamin B_1, riboflavin, inorganic P and urea was estimated daily for 3 periods of 13 days during which the dogs received on certain days test doses of vitamin B_1 ranging from 250 to 10,000 μg.

There was marked individual variation in the daily excretion of vitamin B_1 after a test dose and in only one instance was the extra amount excreted in the ensuing 24 hr. approximately equivalent to the amount of the test dose. With the higher test doses excretion remained high for up to 96 hr. The amount of vitamin B_1 excreted daily was related to the volume of urine, which varied greatly; the concentration in the urine was not so variable. The test doses had no marked effect on the excretion of riboflavin, inorganic P or urea. It is concluded that a test of the type described to determine the vitamin B_1 status of dogs is of doubtful clinical value.—J. S. Thomson.

366

MILLER, E. R., SCHMIDT, D. A., HOEFER, J. A. and LUECKE, R. W. **The thiamine requirement of the baby pig.** *J. Nutrition*, 1955, **56,** 423–430. [Dept. Animal Husb., Michigan State Coll., East Lansing.]

Baby pigs taken from the sow at 3 or 4 days of age were given a synthetic milk diet (Abst. 4422, Vol. 24) with no vitamin B_1 for 4 days and then with graded doses of vitamin B_1. An amount of 1·5 mg. vitamin B_1 per kg. dietary solids was required for optimum growth and efficiency of feed utilisation. With intakes below 1·0 mg. per kg. solids, signs of vitamin B_1 deficiency developed. When extra vitamin B_1 was given by injection to 3 deficient pigs, normal weight gain, appetite and heart rate were restored in 2 of them. Blood studies showed no clear change in white cell count or Hb value, but the vitamin B_1 content of the blood was related to that of the diet.

DE BERNARD, B. and LORENZI, G. L. Concentrazione della cocarbossilasi nella cartilagine metafisaria di giovani conigli a dieta carente di vitamina B_1. [**Concentration of cocarboxylase in the metaphyseal cartilage of young rabbits on a diet deficient in vitamin B_1.**] *Arch. Sci. biol., Bologna*, 1955, **39,** 308–312. [Ist. Chim. Biol., Univ. Pavia.]

In further studies on the concentration of cocarboxylase in metaphyseal cartilage in relation to growth (see Absts. 3493, 4866, Vol. 25), 20 Flemish Giant rabbits, aged 25 days and weighing about 650 g., were maintained for from 25 to 30 days on a diet without vitamin B_1. Eight received daily a subcutaneous injection of 0·5 mg. vitamin B_1, and the other 12 had in their food 2 g. daily of streptoguanidine. Cocarboxylase was estimated in the cartilage by a manometric technique in a Warburg apparatus. The deprived rabbits did not grow, so the amount of metaphyseal cartilage available for analysis was much less than from the non-deprived. The mean value for cocarboxylase, in μg. per g. fresh tissue, was 5·2 (range 3·7 to 6·9)

for the non-deprived and 0 for all but 3 (0·15, 2·0, 2·9) of the deprived. For comparison, values are given for 7 rabbits 30 days old; the mean was 16·4 with range 10·2 to 31·2 (Abst. 3493, Vol. 25).

Siliprandi, N., Boffi, V. and Lucarelli, A. **Action of insulin on thiamine phosphorylation *in vitro*.** *Nature*, 1955, **176,** 219–220. [Inst. Biol. Chem., Univ. Rome.]

Formation of cocarboxylase was studied *in vitro* in homogenates of liver and in preparations of thiaminokinase from normal rats and rats made diabetic with alloxan, with and without addition of insulin. Insulin had no significant effect in increasing the amount of cocarboxylase found except when it was incubated with serum from normal or diabetic rats for 30 min. before being added to the enzyme system. Serum by itself did not affect phosphorylation and the action of insulin was concluded to be concerned directly with phosphorylation of vitamin B_1 and not with activation of the thiaminokinase.—A. M. Copping.

372

Bamann, E. and Schuegraf, A. Dephosphorylierung der Aneurinphosphate durch Cer und Lanthan. [**Deposphorylation of vitamin B_1 phosphates by cerium and lanthanum.**] *Biochem. Ztschr.*, 1955, **326,** 507–510. [Inst. Pharmazie, Univ. Munich.]

Both cerium and lanthanum catalysed the dephosphorylation of vitamin B_1 pyrophosphoric acid and vitamin B_1 monophosphoric acid in weakly alkaline media. The segregation of terminal phosphate residues was greater with Ce and the hydrolysis of vitamin B_1 monophosphoric acid was greater with La.—D. Duncan.

373

Castellani, A. and De Bernard, B. Contenuto di cocarbossilasi nel fegato di ratti albini trattati con adrenocromo. [**Cocarboxylase content of the liver of white rats treated with adrenochrome.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 1135–1137. [Ist. Chim. Biol., Univ. Pavia.]

Cocarboxylase was estimated in the liver of 2 groups of 10 male rats weighing about 150 g., of which one received a subcutaneous injection of 700 μg. adrenochrome per 100 g. bodyweight daily for 3 days. The mean value, expressed as μg. vitamin B_1 diphosphate per g. fresh tissue, was for the rats given adrenochrome 9·03 with range 3·45 to 12·65, and for those not given it 12·52 with range 8·90 to 15·00. The decrease of 28 per cent. was statistically significant.—E. M. Hume.

374

Mouriquand, G., Edel, V. and Chighizola, [R.]. Nouvelles remarques sur le choc thiaminique. Action comparée du chlorhydrate et du monophosphate de thiamine. [**New notes on shock due to vitamin B_1. Comparison of the effects of vitamin B_1 hydrochloride and monophosphate.**] *Presse méd.*, 1955, **63,** 1193–1194. [Lyons.]

In a brief general article, experimental work with pigeons is quoted showing that the monophosphate of vitamin B_1, when given in the same doses, had the same antiberiberi action as the hydrochloride but was about 5 times less liable to produce fatal shock on parenteral administration. Neither salt alone would completely restore vestibular function to normal, for which a complete diet was necessary.—L. Wills.

RINDI, G., PERRI, V. and FERRARI, P. Cortisone ed avitaminosi B_1 del ratto. [**Cortisone and vitamin B_1 deficiency in the rat.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26**, 66–78. [Ist. Fisiol. Umana, Univ. Pavia.] German, French, and English summaries.

Twelve groups of rats weighing from 95 to 105 g. were maintained on a diet containing, per cent., purified casein 18, wheat starch 65, olive oil 10, cod liver oil 2 and salts 5. Six groups had an addition of 7 per cent. dried yeast to the diet, and 6 groups a mixture of B vitamins without vitamin B_1. Of those deprived and not deprived of vitamin B_1, pairs of groups had a daily dose of 1 or 4 mg. deoxycorticosterone acetate or none. One of each pair of groups was killed after 10 days and the other after 20 days. Pyruvate was estimated in the blood and vitamin B_1 by the thiochrome method in the liver, leg muscles and brain.

Weight increase was adversely affected by deprivation of vitamin B_1 or by administration of either dose of cortisone. The combined effect was little greater than that of either factor singly. The mean value for blood pyruvate was increased by deprivation and by the larger dose of cortisone, particularly after 20 days. The highest value was obtained after deprivation with cortisone for 20 days. The mean vitamin B_1 content of the liver, muscle and brain was decreased by deprivation and by administration of the 4 mg. dose of cortisone. The decrease after 20 days' deprivation was greater than after 10, but after 20 days' administration of cortisone was not significantly greater than after 10. There was no summation of effects when both treatments were given, the effect of deprivation being actually somewhat less when cortisone was given. The results are analysed statistically.—E. M. Hume.

380

DE CARO, L., RINDI, G., FERRARI, G. and PERRI, V. Andamento dell'avitaminosi B_1 in ratti ipofisectomizzati e in ratti surrenectomizzati. [**The course of vitamin B_1 deficiency in hypophysectomised and in adrenalectomised rats.**] *Arch.. Sci. biol., Bologna*, 1955, **39**, 352–368. [Ist. Fisiol. Umana, Univ. Pavia.]

Male rats weighing about 100 g. were given a diet deficient in vitamin B_1 for up to 35 days, beginning 5 days after removal of the pituitary gland. Similar rats given the same diet had the adrenal glands removed after varying periods of deprivation, and were then killed after a further 4 to 6 days of the diet. Corresponding groups were maintained on the deficient diet without operation and on a complete diet without hypophysectomy. Neither operation significantly affected the rate of depletion of vitamin B_1 in the liver, muscle and brain. After removal of the pituitary gland, blood pyruvate increased during deprivation much less than in rats with the gland intact; the weight of the adrenal glands decreased slightly, but increased in intact deprived rats. In adrenalectomised rats blood pyruvate increased only slightly during deprivation.—E. M. Hume.

CERECEDO, L. R. **Symposium on the antimetabolites. Thiamine antagonists.** *Amer. J. Clin. Nutrit.*, 1955, **3**, 273–281. [Dept. Biochem., Fordham Univ., New York.]

382

EICH, S. and CERECEDO, L. R. **Effects of certain thiamine analogs on the enzymatic decarboxylation of α-ketobutyric acid.** *Arch. Biochem. Biophys.*, 1955, **57**, 285–287. [Dept. Chem., Fordham Univ., New York.]

With conditions similar to those described previously (Abst. 4410, Vol. 24), decarboxylation of α-ketobutyrate by α-carboxylase was studied. Oxythiamine diphosphate inhibited decarboxylation, and its effect was conditioned by the order in which the enzyme and analogue were added to the reaction mixture. If the analogue was added after the enzyme it almost failed to cause inhibition. Oxythiamine and neopyrithiamine had no effect.

A. M. Copping.

383

FUJITA, A., OKAMOTO, T. and NOSE, Y. **Antithiamine factors of ferns.** *J. Vitaminol., Japan*, 1954, **1**, No. 2, 24–38. [Biochem. Inst., Kyoto Prefectural Univ.]

The nature of antivitamin B_1 factors in Japanese fern was investigated with extracts obtained from dried fern with a phosphate buffer at *p*H 7 and a temperature below 60° C. The thermolabile

antivitamin B_1 factor was inactivated by heating at 100° C. for 30 min., and showed optimum activity at 50° C. and *p*H 6. The activity of the thermostable factor increased with temperature up to 100° C. The thermostable factor could be dialysed through cellophane. One of the products of its action on vitamin B_1 was identified as thiochrome. It was activated by O_2, Cu and Mn and inhibited by cysteine. The same substances had the opposite effect on the thermolabile factor, which was activated also by some organic bases. From these and other properties it was concluded that the thermolabile factor resembled thiaminase in its properties but that the thermostable factor was probably not enzymic in nature.—A. M. Copping.

384

MATSUKAWA, D., CHANG, S., FUJIMIYA, M. and MISAWA, H. **Studies on the thiamine deficiency due to bacterial thiaminase. 2. Experiments on hens.** *J. Vitaminol., Japan*, 1954, **1**, No. 2, 53–55. [Dept. Med., Sch. Med., Niigata Univ., Asahi-Machi.]

For part 1 see Abst. 4874, Vol. 25.

When *Bacillus thiaminolyticus* was given to hens on a normal diet of whole rice and greenstuff, thiaminase was detected in the faeces within 6 days and signs of vitamin B_1 deficiency appeared in about 40 days. Hens on the same diet with no *B. thiaminolyticus* remained healthy and their tissues contained more vitamin B_1 than those of hens receiving the bacillus.—A. M. Copping.

385

MAJORI, L. Beri-beri sperimentale nel colombo in equilibrio tiaminico in seguito ad ingestione di *Venerupis decussata*. 2. [**Experimental beriberi in the pigeon in a state of vitamin B_1 balance, after consuming *Venerupis decussata*. 2.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 785–787. [Ist. Igiene, Univ. Messina.]

Groups of 3 or 5 pigeons were given daily 29 g. polished rice. One group received in addition daily 1 g. wheat and 20 g., uncooked, of the mollusc *Venerupis decussata*, taken from Lake Ganzirri. Another group received the same with the mollusc boiled for 10 min., and a third group was given daily 5 μg. vitamin B_1 and 20 g. raw mollusc. The 2 groups receiving the raw mollusc showed the first signs of beriberi in 7 or 8 days; they were injected twice with a total of 0·025 g. cocarboxylase and given a diet of wheat, which brought about their cure. The group given boiled mollusc still showed no sign of beriberi after 3 months. No evidence was thus obtained for the presence of a toxin other than thiaminase in *Venerupis*.—E. M. Hume.

386

SIVARAMAKRISHNAN, V. M. and SARMA, P. S. **The influence of thiamine on nitrogen metabolism.** *Biochim. biophys. Acta*, 1955, **18**, 153–154. [Lab. Biochem., Univ. Madras.]

When green gram seeds were germinated in a medium containing neopyrithiamine the content of asparagine was less, that of glutamine was slightly greater, and that of free ammonia much greater, than in seeds without neopyrithiamine. The disturbance of N metabolism was partly reversed if vitamin B_1 and neopyrithiamine were present together, and almost completely reversed if cocarboxylase was present.

Evidence of impaired N metabolism was obtained also in rats given neopyrithiamine; injection of glutamate into them precipitated acute signs of vitamin B_1 deficiency.—A. M. Copping.

387

SCHOFIELD, F. W. and ROBERTSON, A. **Oedema disease (entero-toxaemia) in swine. 1. Experiments designed to reproduce the disease.**

SCHOFIELD, F. W. and DAVIS, D. **2. Experiments conducted in a susceptible herd.**

SCHOFIELD, F. W. and NIELSEN, S. W. **3. The use of thiamine in its prevention and cure.** *Canad. J. Comp. Med.*, 1955, **19**, 240–242; 242–245; 245–250. [Dept. Pathol., Ontario Vet. Coll., Guelph.]

1. Attempts to produce oedema disease by sudden and drastic change of diet, by adding the ingesta of pigs which had died of the disease to the feed, by reducing peristalsis through giving opium, by movement to and from market, by intravenous injection of filtrates from the stomach and intestine of infected pigs, and by giving unidentified bacteria isolated from pig intestine, failed in experiments with pigs at weaning, the age at which oedema disease usually occurs.

2. In an experiment with pigs from a herd known to be susceptible, streptomycin was given to one group but oedema disease did not develop in either group, and no conclusion could be reached. In another experiment a vaccine was prepared from *Bacterium coli*, which is frequently found in faecal cultures from oedema disease, and one group of pigs was treated with the vaccine; 2 of them died, but results were inconclusive. When susceptible and normal pigs were reared in similar conditions and on similar rations, 4 out of the 6 susceptible pigs died showing signs of oedema disease; the normal pigs were not affected. It was thought that toxogenic organisms were present in the intestines of the susceptible pigs. The use of different standards of feeding for the sows, one standard being comparable with that used in the susceptible herd, did not affect the incidence of oedema disease in the offspring. In this series of

experiments there was no evidence that the disease was contagious, or that it was due to the feed.

3. Experiments designed to test the efficacy of vitamin B_1 for prevention and cure of oedema disease showed that it was of no value, and analysis of feeds in use where the disease had occurred showed that they contained enough vitamin B_1, and that vitamin B_1 deficiency was not the cause.

RIBOFLAVIN

388

ADAMS, D. H. **Liver catalase in the riboflavin-deficient mouse.** *Biochem. J.*, 1955, **60,** 568–572. [Dept. Cancer Res., London Hosp. Med. Coll., E.1.]

When weanling male mice were maintained for 5 or 6 weeks on a purified diet lacking riboflavin, or were pair-fed on the same diet with riboflavin added, or on a normal diet, the catalase activity of the liver did not rise to the adult values usually attained within 3 weeks. Injection of testosterone restored the catalase activity to normal in the pair-fed mice but not in those deprived of riboflavin. In female mice deprivation of riboflavin did not affect the catalase activity but it did prevent the rise in response to injection of testosterone.

A single injection of a riboflavin antagonist in adult male mice caused a fall in catalase activity within 48 hr., with a subsequent rise to normal. The antagonist did not affect catalase activity in castrated male mice. In riboflavin deficiency there was no change in Hb values.—A. M. Copping.

NAVAZIO, F. and SILIPRANDI, N. **Flavines in experimental diabetes.** *Experientia,* 1955, **11,** 280–281. [Inst. Biol. Chem., Univ. Rome.] Italian summary.

With the method of Bessey *et al.* (Abst. 3377, Vol. 19) it was shown that fresh liver tissue from rats with alloxan diabetes contained less riboflavin and less flavin adenine dinucleotide than normal liver tissue. Administration to the rat of riboflavin or flavin mononucleotide with adenosine triphosphate restored the liver riboflavin and flavin enzyme systems to normal.—A. M. Copping.

BERNARDINI, A. and LINO, A. Le modificazioni del contenuto in vitamine B dei tessuti di animali irradiati. 1. Le modificazioni della riboflavina. [**Changes in the content of B vitamins in the tissues of animals treated with X-rays. 1. Changes in the riboflavin.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 1075–1077. [Ist. Patol., Univ. Catania.]

Rats weighing about 160 g. were fed on a purified, complete diet. Groups of 7 were given a single exposure to X-rays over the head only, over the chest and abdomen, and over the whole body; another group was not exposed at all. Fifteen days later they were killed and riboflavin was estimated by the fluorescence technique of Gourévitch (Abst. 304, Vol. 7) in the liver, muscles and brain. The riboflavin content in the tissues of all 3 groups of rats treated with X-rays was low, especially so in the brain of those irradiated over the head.—E. M. Hume.

HENDRICKX, H. and DE VLEESCHAUWER, A. Het gebruik van wei en afgeroomde melk bij de biosynthese van vitamin B_2 door Eremothecium ashbyii. [**The use of whey and skimmed milk for biosynthesis of vitamin B_2 with *Eremothecium ashbyii.*]** *Meded. Landbouwhogesch. Gent.*, 1955, **20,** No. 2, 229–246. [Rijkszuivelstat., Melle.] French, English and German summaries.

In the Netherlands at least some tens of millions of litres of whey go to waste and foul the watercourses. Cost of processing and limitations of usefulness have so far made utilisation impossible. Literature on the use of whey as a substrate for the growth of micro-organisms is reviewed. In the present study a stock culture of *Eremothecium ashbyii* was maintained on agar slopes prepared from 2 g. yeast extract, 3 g. peptone, 10 g. glucose and 15 g. agar per litre. The whey was from a cheese factory, from pasteurised milk. Tests are described in detail. On the average, whey cultures with 1, 2·5 or 5 per cent. sucrose produced 435, 665 or 755 μg. riboflavin per ml. A mixture of half whey and half skimmed milk with the same additions of sucrose produced from 440 to 800, mean 630; 770 to 1500, mean 1150; and 1125 to 2200,

mean 1575, μg. riboflavin per ml. Skimmed milk alone gave wide variations in yield. Yeast extract gave no extra yield.

The conclusion is that the use of whey or, better, whey and skimmed milk with a fermentable sugar as a culture medium for the production of riboflavin may solve the problem of the whey and skimmed milk surpluses.—I. Leitch.

ODRIOZOLA, C. Determinación fluorométrica de riboflavina en frutas. [**Fluorimetric estimation of riboflavin in fruit.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 130–141.

Riboflavin was estimated by the methods of Scott *et al.* (Abst. 4172, Vol. 16) and of Roth (Abst. 3408, Vol 20) in the edible portion of the fresh fruit; 2 samples of 30 varieties were tested by each method. Those having the highest content of riboflavin, in μg. per 100 g. for the 2 samples, were passion fruit 91 and 110, prickly custard-apple (*Anona muricata*) 103 and 105, lucuma 131 and 113, and avocado pear 117 and 120. The poorest sources were coconut and quince.

NICOTINIC ACID (NIACIN)

395

JANSEN, B. C. P. Nicotinezuur (amide), (pellagra-preventing factor; niacine). [**Nicotinic acid (amide), the pellagra-preventive factor, niacin.**] *Voeding*, 1955, **16**, 646–652.

A chapter for a new textbook of nutrition (Abst. 3588, Vol. 24; see also Absts. 296, 342).

396

HOPPER, J. H. and JOHNSON, B. C. **The production and study of an acute nicotinic acid deficiency in the calf.** *J. Nutrition*, 1955, **56**, 303–310. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Male calves were given a synthetic milk on the second day of life. When the milk contained 0·17 per cent. tryptophan and 2·60 mg. nicotinic acid per litre they grew well and showed no unusual sign for from 24 to 38 days. If nicotinic acid was omitted appetite failed after 2 days and severe scouring occurred. Administration of nicotinic acid orally or parenterally restored appetite and weight gain. Subsequent deprivation of nicotinic acid did not cause a repetition of the disturbance.—A. M. Copping.

CASTELLANI, L. and BERTOLA, G. Steatosi da CCl_4 e metionina epatica. [**Fatty liver caused by CCl_4 and liver methionine.**] Nicotamide e metionina epatica. [**Nicotinamide and liver methionine.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 1204–1205; 1206–1207. [Ist. Clin. Med., Univ. Genoa.]

Fifteen adult guineapigs receiving the laboratory diet were made to inhale CCl_4 vapour for 10 min. daily for 20 days. The degree of fatty liver produced was determined on 5 of the animals, and the concentration of free methionine in the liver was estimated by the method of Albanese *et al.* (Abst. 2889, Vol. 14) for the other 10 and for 10 not treated with CCl_4. The mean value in mg. free methionine per 100 g. fresh liver was for the poisoned animals 0·75 with range 0·62 to 0·94, and for those not poisoned 1·58 with range 1·30 to 1·72.

Free methionine was estimated by the same method in the liver of 10 guineapigs given parenterally 10 mg. nicotinamide daily for 10 days, and of 10 not given it. The mean value in mg. free methionine per 100 g. fresh liver tissue was 0·98 with range 0·83 to 1·06 for those given nicotinamide and 1·51 with range 1·42 to 1·85 for those not given it.—E. M. Hume.

398

RICCI, C. Ricerche sull'ossidazione del succinato nel fegato di ratti trattati con nicotinamide. [**Oxidation of succinate in the liver of rats treated with nicotinamide.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 1040. [Ist. Chim. Biol., Univ. Genoa.]

A larger amount of triphenyltetrazolium was reduced in presence of succinate by homogenates of whole liver from rats given extra nicotinamide than from rats not given it. In absence of succinate there was no difference. There was no difference in the behaviour of mitochondria isolated from the homogenates. Tests for succinic oxidase depending on the reduction of cytochrome *c* showed no difference in the behaviour of liver homogenates from the 2 groups of rats.

E. M. Hume.

VILLA, L. and DIOGUARDI, N. In tema di metabolismo epatico e di patologia enzimatica. Considerazioni intorno alle cosiddette "ossidazioni di emergenza". [**Metabolism in the liver and enzyme disturbances. The so-called "emergency oxidations".**] *Acta vitaminol.*, 1955, **9**, 97–100. [Ist. Clin. Med. Gen., Univ. Milan.] French, English, German and Spanish summaries.

Experiments were made of the same type as those previously described (Absts. 1951, 4890, Vol. 25), which were interpreted as showing that in rats after fasting, or when fed on a low-protein diet, oxidation by liver homogenates followed a path which was not that of the Krebs cycle. Nicotinamide increased such "emergency" oxidation, but reduced oxidation by liver homogenates from normal rats. Sub-lethal poisoning with the toxin of the fungus *Amanita phalloides* provided another set of conditions in which such emergency oxidation took place.—E. M. Hume.

La Rosa Bazalar, D. Influencia de la nicotinamida sobre la hiperglucemia de la diabetes aloxánica. [**Effect of nicotinamide on the hyperglycaemia of alloxan diabetes.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4,** 245–255.

Six male and 6 female rabbits weighing from 1150 to 2360 g. were made diabetic by injection of from 100 to 150 mg. alloxan per kg. bodyweight and, a few hours later, when the blood sugar had risen, received intraperitoneally 0·005, 0·01 or 0·015 mg. nicotinamide per kg. bodyweight. A drop in blood sugar followed, lasting up to 24 hr. Male animals were more sensitive than females. Several rabbits died with very low blood sugar values.—D. Duncan.

401

Henderson, L. M., Koski, R. E. and D'Angeli, F. **The rôle of riboflavin and vitamin B_6 in tryptophan metabolism.** *J. Biol. Chem.*, 1955, **215,** 369–376. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

In normally fed rats and in animals deprived of riboflavin or vitamin B_6, excretion of nicotinic, quinolinic and xanthurenic acid in response to doses of tryptophan, kynurenine or 3-hydroxyanthranilic acid was studied. Deprivation of vitamin B_6 reduced the excretion of metabolites containing the pyridine nucleus. Lack of riboflavin had no such effect. In rats deprived of riboflavin, excretion of xanthurenic acid rose in response to administration of tryptophan, but the xanthurenic acid excreted in response to kynurenine and 3-hydroxykynurenine fell slightly. Paper chromatograms of urine from rats deprived of riboflavin and receiving tryptophan showed the presence of compounds likely to be excreted if hydroxylation of kynurenine was impaired. In vitamin B_6 deficiency blocking of anthranilic acid formation from kynurenine appeared to be the characteristic defect in the metabolism of tryptophan.—A. M. Copping.

VITAMIN B_6 (PYRIDOXINE, ADERMIN)

406

PARRISH, W. P., LOY, H. W. (Jr.) and KLINE, O. L. **A study of the yeast method for vitamin B_6.** *J. Assoc. Off. Agric. Chem.*, 1955, **38,** 506–513. [Food and Drug Admin., Dept. Health, Washington, D.C.]

Modifications were made in the method of Atkin *et al.* (Abst. 1099, Vol. 13) in which *Saccharomyces carlsbergensis* is used to estimate vitamin B_6. Results were more accurate when the yeast inoculum was taken from a culture growing in the medium to be used for the test and when the basal medium and test solutions were sterilised separately. Separate sterilisation was most important when pyridoxal and pyridoxamine were under test, since they reacted with heated sugars. Incubation at 25° C. for from 22 to 28 hr. with constant agitation of the tubes gave consistent results; the growth response to pyridoxine and pyridoxal was about the same but to pyridoxamine it was only from 50 to 60 per cent. of that to pyridoxine.

A. M. Copping.

407

FASELLA, P., LIS, H. and SILIPRANDI, N. Studio elettroforetico di alcune reazioni di transaminazione. **[Electrophoretic study of some transamination reactions.]** *Riv. Ist. sieroterap. ital.*, 1955, **30,** 206–210. [Ist. Chim. Biol., Univ. Rome.] English summary.

Mixtures of Na pyruvate with pyridoxamine and of alanine with pyridoxal, with a suitable buffer including aluminium ammonium sulphate, were heated for an hour at 100° C., and subjected to electrophoresis on paper and on a cellulose column, the resulting substances being identified by exposure to ultraviolet light and by spraying with *p*-aminoacetophenone and ninhydrin. In the first mixture spots corresponding with pyridoxal and alanine appeared, and in the second with pyruvate and pyridoxamine; in both there was also a highly fluorescent intermediate substance, which was without free amine or aldehyde groups and on hydrolysis at 90° C. gave rise to alanine and pyridoxal. The presence of Al was necessary for its production.—E. M. Hume.

408

HAWKINS, W. W. **Skin symptoms of vitamin-B_6 deficiency in the dog.** *Science*, 1955, **121,** 880. [Maritime Reg. Lab., Nat. Res. Counc., Halifax, N.S.]

Severe skin lesions occurred in only 3 of 9 puppies receiving a diet lacking vitamin B_6 and containing deoxypyridoxine and 40 per cent. casein. The lesions were cured when deoxypyridoxine was withdrawn and pyridoxine given. Skin lesions did not occur in adult dogs deprived of vitamin B_6 and showing blood changes typical of the deficiency.—A. M. Copping.

409

HAWKINS, W. W. and YOUNG, E. G. **Nitrogen metabolism in vitamin B_6 deficiency in the dog.** *Amer. J. Physiol.*, 1955, **181,** 196–202. [Dept. Physiol., Univ. Manitoba, Winnipeg.]

Dogs were given purified diets lacking vitamin B_6 and containing 18 or 40 per cent. casein. Some dogs were given 1·5 mg. pyridoxine hydrochloride daily, and others had deoxypyridoxine to make the deficiency more severe. Growth was not significantly affected by lack of vitamin B_6 and there was no rise in the concentration of urea in the blood or in the amount of N excreted, a result in contrast with findings in the rat deprived of vitamin B_6. Administration of deoxypyridoxine caused a small increase in N excretion. There was no significant difference in the concentration or distribution of proteins, N.P.N. or urea N in the blood between the several groups of dogs. No excess urea or amino-N appeared in the blood after test doses of urea or alanine, even after long periods of vitamin B_6 deprivation.—A. M. Copping.

410

BEATON, J. R. and OZAWA, G. **Activity of liver glutaminases in vitamin B_6-deficient rats.** *J. Biol. Chem.*, 1955, **214,** 685–691. [Dept. Pub. Health Nutrit., Univ. Toronto, Ont.]

The activities of the phosphate-activated glutaminase I and the pyruvate-activated glutaminase II were estimated in preparations of rat liver by methods previously described (Abst. 3532, Vol. 25; *Proc. Soc. Exp. Biol. Med.*, 1954, **87,** 238). With pair-fed groups of rats with and without vitamin B_6 in a purified diet, glutaminase I was significantly higher and glutaminase II significantly lower in the deprived than in the non-deprived animals. Addition of pyridoxal phosphate to extracts of the liver from deprived rats restored only a small part of the activity of glutaminase II. Dialysis of liver extracts from normally fed rats caused loss of glutaminase II activity. Addition of pyridoxal phosphate to the dialysed extracts increased glutaminase II activity in some but not in others. Free glutamine was estimated in liver and kidney tissue and gave no indication that decrease of enzyme activity was directly related to decrease of available substrate.

A. M. Copping.

411

ZBINDEN, G. and STUDER, A. Vergleichende Untersuchungen über die Wirkung von Pyridoxin, Pyridoxal-5′-phosphat und Pyridoxal-isonicotinylhydrazon auf die experimentelle Isoniazid-"Neuritis" der Ratte. [**Comparative studies of the effects of pyridoxine, pyridoxal-5′-phosphate and pyridoxal *iso*nicotinylhydrazone on experimental isoniazide "neuritis" in the rat.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26**, 130–137. [Med. Lab., Hoffmann La Roche A.G., Basle.] French and English summaries.

When rats were injected with 250 or 500 mg. isoniazide per kg. bodyweight daily for 15 days or longer, severe degeneration occurred in the peripheral nerves. The degeneration was prevented if pyridoxine or pyridoxal phosphate, 10 to 50 mg. per kg. bodyweight, was injected subcutaneously, and the two substances were equally effective.

Pyridoxal *iso*nicotinylhydrazone, which had a small antituberculosis activity, produced slight nerve degeneration when it was given in large doses of 1000 mg. per kg. bodyweight.

A. M. Copping.

412

BEATON, J. R. ***In vitro* studies on carbohydrate metabolism in the vitamin-B_6-deprived rat.** *Canad. J. Biochem. Physiol.*, 1955, **33**, 562–567. [Dept. Pub. Health Nutrit., Univ. Toronto, Ont.]

The disturbance of carbohydrate metabolism in rats deprived of vitamin B_6 (Absts. 2930, Vol. 23; 1963, Vol. 25) was investigated by enzyme studies on tissues from rats deprived of vitamin B_6 and from pair-fed non-deprived animals. The utilisation of glucose by leg muscle and the cytochrome oxidase activity of liver tissue showed no significant difference between the groups. In vitamin B_6 deficiency liver catalase activity rose in female but not in male rats; liver aldolase activity fell and alkaline phosphatase of the blood rose. The relation of the findings to the variations recorded for deprived rats in blood values for sugar, pyruvate and lactic acid, and in liver glycogen, is discussed.

A. M. Copping.

414

UMBREIT, W. W. **Symposium on the antimetabolites. Vitamin B_6 antagonists.** *Amer. J. Clin. Nutrit.*, 1955, **3**, 291–297. [Merck Inst. Therap. Res., Rahway, N.J.]

415

MAKINO, K. and KINOSHITA, T. **On the atoxopyrimidine action of B_6 group-vitamins.** *J. Vitaminol., Japan*, 1954, **1**, No. 2, 14–17. [Dept. Biol. Chem., Sch. Med., Kumamoto Univ., Ninomaru.]

When mice receiving a purified diet without vitamin B_6 were given injections of the pyrimidine component of vitamin B_1 severe convulsions occurred and the animals died. Convulsions occurred also when the diet contained vitamin B_6 but their severity was related to the size of the dose of pyrimidine. Simultaneous injection of pyridoxine or pyridoxamine prevented the toxic effects of pyrimidine. The relation of structure to biological antagonism is discussed with reference to pyrimidine and derivatives of pyridoxine.

A. M. Copping.

PANTOTHENIC ACID

416

BIANCHINI, P. Estrazione del coenzima "A". [**Extraction of coenzyme A.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 1378–1379. [Lab. Ric. "Crinos", Indust. Farmacobiol., Milan.]

A method is described in detail for preparing coenzyme A from pig's liver. The yield was never greater than between 600 and 700 mg. from 20 kg. fresh liver. It was considered that it could be improved, and that the fault probably lay in the kind of carbon used in an adsorption process of purification. The matter is being further investigated.—E. M. Hume.

417

FIDANZA, A., GIUNCHI, G., SCURO, L. A. and SORICE, F. Eliminazione urinaria e fecale di acido pantotenico in ratti alimentati con dieta sintetica priva della vitamina ed addizionata di aureomicina. [**Urinary and faecal excretion of pantothenic acid in rats fed on a synthetic diet without the vitamin and with added aureomycin.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 979–983. [Ist. Fisiol., Univ. Rome.]

Rats weighing about 50 g. received a complete diet or the same without pantothenic acid, with or without 0·05 per cent. aureomycin. After 6

weeks, when the rats deprived of pantothenic acid were showing signs of deficiency, 2 rats receiving each diet were isolated, and urine and faeces were collected daily for 5 days. Free pantothenic acid was estimated in them with *Lactobacillus arabinosus* ATCC 8014. The mean values in μg. pantothenic acid excreted in the urine in 24 hr. for the rats separately was, for the diet with pantothenic acid 134·4 and 163·0, for the diet without pantothenic acid 12·2 and 9·1, and for the diet without pantothenic acid but with aureomycin 40·0 and 42·0. The corresponding values for the faeces in μg. per 24 hr. were 47 and 63, 3·4 and 4·8, and 17·8 and 13·8.—E. M. Hume.

418

DINNING, J. S., NEATROUR, R. and DAY, P. L. **A biochemical basis for the interrelationship of pantothenic acid and methionine.** *J. Nutrition*, 1955, **56,** 431–435. [Dept. Biochem., Univ. Arkansas Sch. Med., Little Rock.]

Weanling rats were given a basal diet deficient in sulphur amino-acids and in pantothenic acid with varying supplements of methionine and pantothenic acid. After 30 days 50 mg. guanidoacetic acid per 100 g. bodyweight was given by stomach tube and the amount of guanidoacetic acid, creatinine and creatine was measured in the urine during 24 hr. The extent of methylation of guanidoacetic acid was not significantly affected by the amount of pantothenic acid or methionine in the diet. Urinary excretion of creatine was higher in rats given little or no methionine or pantothenic acid. Individual variations were great in the excretion of all constituents.

Coenzyme A was estimated in the liver and the amount bore a relation to the amounts of pantothenic acid and methionine in the diet. The findings showed an interrelation between pantothenic acid and methionine since the latter could increase the liver content of coenzyme A when the former was present in limiting amounts, by which the severity of the pantothenic acid deficiency would be decreased.—A. M. Copping.

AMICI, A. and TACCHI, V. Sul comportamento dei lipidi totali del fegato di ratti albini dopo somministrazione di acido pantotenico. [**Behaviour of the total lipids in the liver of albino rats after administration of pantothenic acid.**]

AMICI, A. and DOLCINI, C. Sul comportamento del glicogeno epatico, muscolare, cardiaco e della glicemia di ratti albini dopo somministrazione di acido pantotenico. [**Behaviour of glycogen in the liver, muscle, and heart and of the blood sugar in albino rats after administration of pantothenic acid.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 843–844; 845–846. [Ist. Fisiol., Univ. Perugia.]

See Abst. 1968, Vol. 25.

Thirty-six male rats weighing about 200 g. were fasted for 12 hr. Four were killed before subcutaneous injection of 100 mg. pantothenic acid and 4 more after 1½, 2, 2½, 3, 3½, 4, 6 and 12 hr. Total lipids were estimated in the liver. After a small increase, the amount fell up to 2½ hr., but had begun to rise after 3 hr. and continued to do so up to 4 hr., after which it decreased again.

In an experiment with exactly the same plan, blood sugar, and glycogen in the liver, skeletal muscle and heart were estimated. Glycogen in the liver decreased progressively for 3½ hr., then began to rise and had returned to normal after 6 hr. Glycogen in the heart was somewhat low after 2 hr., but quickly recovered; in skeletal muscle the value fluctuated. Blood sugar values fluctuated also.—E. M. Hume.

WRIGHT, L. D., CRESSON, E. L. and DRISCOLL, C. A. **Biological precursors of biotin and/or biotin L-sulfoxide.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 234–236. [Sharp and Dohme, Div. Merck and Co., West Point, Pa.]

During studies to isolate biotin sulphoxide from cultures of *Aspergillus niger*, precursors of biotin and its L-sulphoxide were investigated. Pimelic and azelaic acids were precursors, but not any shorter-chain dicarboxylic acid. Compounds such as Tween 80 with structural relationships to pimelic or azelaic acid were inactive. The effect of dicarboxylic acids of 7- or 9-carbon chain length was not increased in presence of purines, pyrimidines or cystine.—A. M. Copping.

FOLIC ACID (PTEROYLGLUTAMIC ACID)

424

BAKER, H., HUTNER, S. H. and SOBOTKA, H. **Estimation of folic acid with a thermophilic bacillus.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 210–212. [Dept. Chem., Mount Sinai Hosp., New York.]

When the nutritional requirements of thermophilic bacilli were studied, a strain of *Bacillus coagulans* was found to have a requirement which could be satisfied by *p*-aminobenzoic acid or pteroylglutamic acid or folinic acid or other folic acid conjugates. The value of the organism in tests for folic acid and related compounds was demonstrated in metabolism studies on subjects given doses of 5 mg. pteroylglutamic acid. Within 10 hr., from 60 to 80 per cent. of the dose was recovered from the urine. The results with *B. coagulans* were in good agreement with earlier results obtained with *Streptococcus faecalis* by Jukes *et al.* (Abst. 1273, Vol. 18).—A. M. Copping.

425

CARVALHO DA SILVA, A., DE ANGELIS, R. C., PONTES, M. A. and MANSUR GUÉRIOS, M. F. **The domestic cat as a laboratory animal for experimental nutrition studies. 4. Folic acid deficiency.** *J. Nutrition*, 1955, **56,** 199–213. [Dept. Physiol., Fac. Med., Univ. São Paulo.]

For previous parts see Absts. 831, Vol. 21; 1951, Vol. 22.

Folic acid deficiency was produced in cats receiving a purified diet of casein, sucrose, lard, peanut oil and salt mixture, with vitamins and sulphaguanidine or sulphathalidine. Loss of weight, macrocytic anaemia and leucopenia were the signs of deprivation. The results were more uniform in cats which did not have sulphonamide during a preliminary period, and the blood changes appeared to develop more rapidly when sulphonamides were then added to the diet. The average time for appearance of signs was 172 days in cats which had had sulphonamides from the beginning of the experiment, and 85 days after institution of sulphonamides in those which had previously received the diet without folic acid for several months. Blood clotting time was increased and plasma Fe values were low. For full recovery of the normal blood picture a single dose of 2 mg. folic acid was enough. The response was better if vitamin B_{12} or liver extract was given with the folic acid. Bodyweight increased with a single dose of 1 mg. folic acid or 0·8 mg. folinic acid, but the red and white cell counts were not normal.

NELSON, M. M., WRIGHT, H. V., ASLING, C. W. and EVANS, H. M. **Multiple congenital abnormalities resulting from transitory deficiency of pteroylglutamic acid during gestation in the rat.** *J. Nutrition*, 1955, **56,** 349–363. [Inst. Exp. Biol., Univ. California, Berkeley.]

When a diet lacking pteroylglutamic acid was given to rats for 24, 48 or 72 hr. at some period during the first 14 days of gestation, abnormalities were produced in the young when the deprivation for 48 or 72 hr. occurred after the seventh day, that is, after implantation. All the embryos were resorbed when the rats were deprived from the 7th, 8th or 9th day of gestation, and all the young were abnormal when the deprivation was from the 10th to the 13th day. The mothers gained weight and remained in good condition notwithstanding. The early phases of embryonic development were more severely affected by deprivation than the

later phases. The time of deprivation appeared to be critically related to the date of implantation. The defects were multiple in the nervous, ocular, skeletal, respiratory, cardiovascular and urogenital systems. The nature of the abnormalities was related to the duration of deprivation and the time after implantation.—A. M. Copping.

427

ASLING, C. W., NELSON, M. M., WRIGHT, H. V. and EVANS, H. M. **Congenital skeletal abnormalities in fetal rats resulting from maternal pteroylglutamic acid deficiency during gestation.** *Anat. Rec.*, 1955, **121,** 775–799. [Inst. Exp. Biol., Univ. California, Berkeley.]

A report is made in detail on the nature and incidence of malformations in the skeleton behind the head of young from normal female rats receiving a diet lacking in pteroylglutamic acid during the latter half of pregnancy (see Abst. 1637, Vol. 23). Every foetus showed defects in the ribs, over 80 per cent. in the radius and ulna, and about 50 per cent. in the scapula, tibia and sternum. Syndactyly occurred in the hind paws of 50 per cent. and in the fore paws of 25. There was dwarfing in the crown to rump measurement of every foetus and in most long bones. The normal sequence of ossification was disturbed in most bones, especially in the segments of the sternum and caudal vertebrae.

The skeletal changes are shown in a series of pictures of bones and in photomicrographs of bone sections. They are discussed with reference to the changes occurring in maternal deficiency of other dietary essentials.—A. M. Copping.

DE BELLA, G. and COLELLA, S. Acido folico e metabolismo basale nel ratto. [**Folic acid and basal metabolism in the rat.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 1307–1309. [Ist. Fisiol., Univ. Naples.]

The B.M.R. was estimated of 2 groups of male rats weighing from 221 to 335 g., which had been maintained for 30 days on a diet without folic acid, one group having received the addition of 100 μg. folic acid per 100 g. diet. The B.M.R. was higher in the rats deprived of folic acid, and when folic acid was subsequently given to them for 15 days, it fell to be the same as in the non-deprived.

REID, B. L. and COUCH, J. R. **Factors affecting the *in vitro* conversion of folic acid to citrovorum factor.** *Arch. Biochem. Biophys.*, 1955, **56,** 388–393. [Dept. Biochem., Texas Agric. and Mech. Coll. System, College Station.]

Homogenates of the liver from chicks aged from 5 to 16 weeks contained an enzyme capable of stimulating conversion of folic acid to citrovorum factor. The enzyme was present in the clear supernatant fluid after differential centrifuging and was partly precipitated with 40 per cent. ethanol. Enzymic conversion was greater in presence of ascorbic acid, Mg, diphosphopyridine nucleotide and adenosine triphosphate, absence of any one of which decreased the amount of citrovorum factor formed. Formate did not appear to be essential. Aminopterin inhibited formation of citrovorum factor. Serine and homocysteine increased the activity of the enzyme system. Livers from chicks deprived of vitamin B_{12} had less of the enzyme activity than livers from chicks which had received an injection of 200 μg. vitamin B_{12} 3 days before they were killed.—A. M. Copping.

FATTERPAKER, P., MARFATIA, U. and SREENIVASAN, A. **Rôle of folic acid and vitamin B_{12} in transmethylations. 2. A sparing effect by formate or methanol on the impairment of creatine metabolism in folic acid deficiency. 3. An influence of folic acid on the methylation of nicotinamide. 4. Non-participation of folic acid in the biosynthesis of methyl compounds from precursors.** *Indian J. Med. Res.*, 1955, **43,** 337–341; 343–348; 349–353. [Dept. Chem. Technol., Univ. Bombay.]

2. Swiss mice were given for 5 weeks a purified diet lacking folic acid, and then formate or methanol with or without folic acid was added to the diet. Mice were killed 5, 8 or 9 days after the changes of diet and creatine was estimated as described previously (Abst. 3558, Vol. 25). Impairment of creatine metabolism as shown by reduced excretion and liver content in mice deprived of folic acid was partly restored by inclusion of formate or methanol in the diet. These supplements had no significant effect on the blood picture in mice deprived of folic acid.

3. Synthesis of N^1-methylnicotinamide *in vivo* and *in vitro* was studied in mice deprived of folic acid; the results given in a preliminary paper (Abst. 1945, Vol. 22) were confirmed and extended. Excess of nicotinic acid was toxic and its toxicity was increased by folic acid deficiency. Vitamin C, choline or folic acid given to deficient mice improved the methylating mechanism and produced increased excretion of N^1-methylnicotinamide.

4. See Abst. 3079, Vol. 24.—A. M. Copping.

PENHOS, J. C. **Relationship between folic acid and sexual hormones in toads and rats.** *Acta physiol. Latino Amer.*, 1955, **5,** 22–30. [Inst. Biol. Med. Exp., Costa Rica 4185, Buenos Aires.]

In immature and mature female toads folic acid enhanced the effect of oestradiol in increasing the weight of the oviduct. Folic acid increased also the effect of testosterone on the weight of the testes and the development of the thumb callosity in immature male toads. The effects of oestrogen and testosterone on immature female and male rats were increased also when folic acid was given with the hormone. Folic acid alone had no effect on the reproductive system of toads or rats.

A. M. Copping.

GRIMBERGEN, A. H. M. Microorganismen, antibiotica en vitamine B_{12} in oud strooisel. [**Micro-organisms, antibiotics and vitamin B_{12} in old litter.**] *Tijdschr. Diergeneesk.*, 1955, **80,** 605–615. [Inst. Moderne Veevoeding "De Schothorst", Hoogland.] English, French and German summaries.

In an attempt to explain the effect of old litter on resistance to infection in poultry and on growth of chicks, litter one or several years old was tested for antibiotic activity, with *Micrococcus pyogenes* var. *aureus* (Oxford strain) as test organism and with particles of litter or an extract of litter. There was no evidence of activity except a temporary development coinciding with a growth of *Thermoactinomyces monospora* which, in pure culture, formed an antibiotic active against *Micrococcus pyogenes* but not against *Bacterium coli*. That and other actinomyces belong to the normal flora of litter but grow only at temperatures between 35° and 50° C. and at *p*H less than 6·5. The antibiotic formed was unstable. A fungus was isolated, probably *Thermoidium sulphureum*, which formed a penicillin-like antibiotic, also unstable. No active spore-forming organism was found.

In two samples of 4-year-old litter and in one of 1-year-old, the amount of vitamin B_{12} was estimated as 0·67, 0·74 and 0·87 μg. per g. dry matter. Chromatographic analysis showed that most of the activity was due to vitamin B_{12}; most of the activity of poultry manure was due to other substances designated factor A.

It is suggested that the effects of old litter may be due, in small part, to uptake of a little antibiotic, in some part to uptake of vitamin B_{12} and possibly also to the uptake of bacterial protein, old litter resembling in this respect the rumen, which may provide an effective supplement to the protein of the diet.—I. Leitch.

VITAMIN B_{12}

437

ØSTERGAARD KRISTENSEN, H. P. **Investigations into the Euglena gracilis method for quantitative assay of vitamin B_{12}.** *Acta physiol. scand.*, 1955, **33,** 232–237. [Inst. Biochem., Univ. Copenhagen.]

In a study of the test for vitamin B_{12} with *Euglena gracilis* as modified by Ross (Abst. 386, Vol. 23) it was found that the sensitivity and accuracy were increased if the *Euglena* cultures were washed and diluted. The medium of strongly growing cultures appeared to contain a thermolabile

factor which inhibited subsequent growth if it was transferred with the cells to a fresh medium.

438

WOLFF, R., KARLIN, R. and PAYSANT, P. A propos du dosage microbiologique de la vitamine B_{12} dans le sérum. [**Microbiological estimation of vitamin B_{12} in serum.**] *Bull. Soc. Chim. biol.*, 1955, **37**, 735–738. [Lab. Chim. Physiol., Fac. Méd., Nancy.]

The method was studied of preparing the sample for estimating vitamin B_{12} in serum with *Lactobacillus leichmannii*. When HCN was added during precipitation of protein and the sample was then autoclaved for 6 min., significantly higher values were obtained than in samples containing no HCN. It is suggested that a thermolabile form of vitamin B_{12} present in serum was stabilised by cyanide treatment.—A. M. Copping.

439

HINE, D. C., DAWBARN, M. C. and SMITH, J. **The effect of copper on the response to vitamin B_{12} and methionine of a mutant strain of *Escherichia coli*.** *Austral. J. Exp. Biol. Med. Sci.*, 1955, **33**, 349–357. [Div. Biochem., C.S.I.R.O., Adelaide.]

The response of *Bacterium coli* mutant to vitamin B_{12} in tube tests was diminished by the presence of copper sulphate in a concentration of 0·0002 per cent. copper. When the organism was using methionine in place of vitamin B_{12} in the medium, the inhibitory effect of copper was much less. Other sulphur compounds such as cystine, homocystine and homocysteine had a protective effect against copper. Thioglycollic acid increased the toxic effect of copper when vitamin B_{12} was the growth factor but not when methionine replaced vitamin B_{12}. It is suggested that copper had an effect on some stage in the synthesis of methionine with which vitamin B_{12} was concerned.

VASQUEZ SANCHEZ, S. DEL S. Determinación colorimétrica de la vitamina B_{12}. [**Colorimetric estimation of vitamin B_{12}.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 386–390.

The method of Boxer and Rickards (Abst. 1836, Vol. 21) which depends on quantitative liberation of cyanogen from vitamin B_{12} by exposure to light was applied to estimate vitamin B_{12} in liver extracts and multivitamin preparations. It gave results in agreement with the stated content of the samples examined. [The paper has a bibliography that belongs elsewhere.]—A. M. Copping.

441

HODGKIN, D. C., PICKWORTH, J., ROBERTSON, J. H., TRUEBLOOD, K. N., PROSEN, R. J. and WHITE, J. G. **The crystal structure of the hexacarboxylic acid derived from B_{12} and the molecular structure of the vitamin.** *Nature*, 1955, **176**, 325–328. [Lab. Chem. Crystallogr., Oxford.]

Direct X-ray analysis of the hexacarboxylic acid isolated from vitamin B_{12} (Abst. 3578, Vol. 25), with a series of calculations of successive degrees of approximation to the correct electron density distribution, provided a solution of the crystal structure for this portion of the molecule and also of a large part of the chemical structure of vitamin B_{12}. A tentative structure corresponding to the empirical formula $C_{63}H_{90}N_{14}O_{14}PCo$ is given with the reservation that the exact number and position of the double bonds are uncertain.

A. M. Copping.

442

BONNETT, R., CANNON, J. R., JOHNSON, A. W., SUTHERLAND, I., TODD, A. R. and SMITH, E. L. **The structure of vitamin B_{12} and its hexacarboxylic acid degradation product.** *Nature*, 1955, **176**, 328–330. [Univ. Chem. Lab., Pembroke St., Cambridge.]

Chemical and X-ray evidence of the nature of vitamin B_{12} crystals and of the hexacarboxylic acid product gave a probable structure. The structure with formula $C_{63}H_{90}N_{14}O_{14}PCo$ contains 6 primary amide groups and one secondary amide joining the aminopropanol residue to the propionic acid grouping in ring D of the nucleus. The vitamin is formulated as a di-ester of phosphoric acid, the free acid group of the phosphate being neutralised by a positive charge on the Co atom, which would account for the relative stability of the phosphate grouping. In defining the conjugated ring system of the nucleus, biogenetic considerations are put forward as additional confirmation of the suggested structure. Full details of the work are to be published in due course.

443

TIXIER, G. and NEUDÖRFFER, J. Facteur intrinsèque. Son dosage dans les préparations opothérapiques. [**Intrinsic factor. Estimation in organotherapeutic preparations.**] *C.R. Soc. Biol.*, 1955, **149**, 249–251.

The method described depends on the ability of intrinsic factor to inhibit the utilisation of vitamin B_{12} in the microbiological method of estimation with *Bacterium coli* 113/3.—H. G. Bray.

444

SKARŻYŃSKI, B., OSTROWSKI, W., NIEWIAROWSKA, A. and ŻAK, Z. Połączenia witaminu B_{12} z białkami. [**Combinations of vitamin B_{12} with proteins.**] *Acta biochim. polon.*, 1955, **2**, 115–127. [Inst. Chem. Physiol. A.M., Cracow.] English and Russian summaries.

By paper electrophoresis and microbiological methods of estimation, it was found that a certain proportion of the vitamin B_{12} in the blood serum of different animals was combined with protein, chiefly with the α-globulin fraction.

The vitamin B_{12} content of the red and white blood cells of horse's blood was about 70 $\mu\mu$g. per ml. erythrocytes and about 500 $\mu\mu$g. per ml. leucocytes. In the former most of the vitamin was bound to non-soluble proteins.

In the liver and kidney cells of the rat most of the vitamin B_{12} was in the mitochondria and was bound to protein. (From summary.)

445

HEDBOM, A. **A native vitamin B_{12}-polypeptide complex.** *Biochem. biophys. Acta*, 1955, **17**, 447. [Inst. Biochem., Univ. Upsala.]

Further purification of a cobalamin polypeptide obtained from beef liver by Wijmenga *et al.* (*Acta haematol.*, 1954, **11**, 372) was achieved by electrophoresis. Two different cobalamin compounds were identified. After treatment with KCN attempts were made to identify the amino-acids of the polypeptide part of the complex. So far, the presence has been demonstrated of glycine, alanine, valine, leucine, threonine, aspartic acid, glutamic acid, tyrosine and histidine, but their sequence in the polypeptide chain has not yet been determined.—A. M. Copping.

446

BRIGGS, G. M. and FOX, M. R. S. **Comparison of vitamin B_{12} and desdimethyl B_{12} activity in the chick.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 318–319. [Lab. Biochem. Nutrit., Nat. Inst. Arthritis and Metabol. Dis., Bethesda, Md.]

A new analogue of vitamin B_{12} in which benzimidazole replaced 5 : 6-dimethylbenzimidazole was obtained from cultures of *Streptomyces griseus*. In growth tests with chicks the desdimethyl analogue had only about 9 per cent. of the activity of crystalline vitamin B_{12}.—A. M. Copping.

447

CAPRARO, V., CRESSERI, A. and BERNINI, G. Osservazioni sull'assorbimento della vitamina B_{12} nel ratto albino. [**Absorption of vitamin B_{12} by white rats.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 1431–1433. [Ist. "Carlo Erba" Ricerch. Terap., Lab. Biol., Milan.]

Groups of from 5 to 9 rats were given a single oral dose of vitamin B_{12} containing ^{60}Co, ranging from 0·025 to 0·1 μg., alone or with intrinsic factor derived from pig's gastric mucosa. Eight hr. later the gastro-intestinal tract was removed ; it was ashed with the faeces, and the radio-activity was measured in the ash. The amount in the ash was not changed by simultaneous administration of intrinsic factor.

In another experiment, when vitamin B_{12} was given to rats made anaemic with phenylhydrazine, regeneration of the red cells was more rapid when intrinsic factor was given also.—E. M. Hume.

448

JACKSON, J. T., MANGAN, G. F., MACHLIN, L. J. and DENTON, C. A. **Absorption of vitamin B_{12} from the cecum of the hen.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 225–227. [Animal and Poultry Husb. Res. Branch, U.S. Dept. Agric., Beltsville, Md.]

Removal of the caecum from hens, fed on a diet of maize and soya bean meal, did not affect the content of vitamin B_{12}, estimated with *Lactobacillus leichmanii*, in the egg or the time required to deplete the egg. If vitamin B_{12} labelled with ^{60}Co was injected into the occluded caecum small amounts of radio-active vitamin B_{12} were found in the blood ; most of the vitamin remained in the caecum, and was probably bound so that it appeared not to be available for absorption. It is suggested that the vitamin B_{12} normally present in the caecum is in the unavailable, bound form. Methionine and sodium sulphate containing ^{35}S were rapidly absorbed from the occluded caecum, which showed that absorption of vitamin B_{12} was not prevented by the conditions of the experiment.

KLEINSORGE, H. and RÖSNER, K. Über die Beeinflussbarkeit der basophilen Substanz jugendlicher Erythrozyten durch Vitamin B_{12}. [**On the possibility of influencing the basophil substance in young erythrocytes with vitamin B_{12}.**] *Folia haematol.*, 1955, **73**, 75–79. [Med. Poliklin., Univ. Jena.]

Blood containing numerous erythrocytes showing basophil stippling was obtained from rabbits given non-lethal doses of lead. Samples of 0·1 ml. were diluted with equal volumes of 3·8 per cent. sodium citrate and of a solution containing from 0·75 to 4·5 μg. vitamin B_{12} per ml. or of physiological saline solution, and incubated for from 1 to 48 hr. at 37° C. There was no difference in the degree of basophil stippling after incubation between the blood preparations with vitamin B_{12} and those without it.—L. Wills.

450

ANSELMI, F. and GUZZON, V. Presunta attività anthistaminica della vitamina B_{12} e potere istaminasico ed istaminopessico del sangue. [**Alleged antihistamine activity of vitamin B_{12}**

and the histaminase and histamine-carrying capacity of the blood.] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 1390–1393. [Ist. Farmacol., Univ. Milan.]

Of 2 groups of 10 non-pregnant female guinea-pigs weighing about 350 g., one group received daily for 10 days a subcutaneous injection of 250 μg. vitamin B_{12} per kg. bodyweight. Five animals in each group were given by subcutaneous injection 3 mg. per kg. bodyweight of the antihistamine drug pyribenzamine; 15 min. later the same animals were given histamine subcutaneously. Heart blood was taken from all the animals 45 min. later, and tested on isolated guineapig intestine in presence of histamine. No evidence was obtained that treatment with vitamin B_{12} exercised any protection against the action of histamine.—E. M. Hume.

451

PASETTO, N. Influenza della vitamina B_{12} sulla attività beta-glucuronidasica del fegato, milza e rene. [**Influence of vitamin B_{12} on the β-glucuronidase activity of the liver, spleen and kidneys.**] *Sperimentale, Sez. Chim. biol.*, 1954, **5,** 21–24. [Ist. Clin. Obstet. Ginecol., Univ. Genoa.]

In the liver, kidneys and spleen of normally fed rabbits weighing from 2·0 to 2·5 kg., the β-glucuronidase activity was greater, especially in the liver, in 7 rabbits that had been injected daily for 10 days with 5 μg. vitamin B_{12} than in 3 that had had no injection.—E. M. Hume.

452

BENNETT, M. A., HELLERMAN, J. and DONNELLY, A. J. **Influence of vitamin B_{12} on liver disease due to a "labile methyl"-free diet.** *Cancer Res.*, 1955, **15,** 398–402. [Lankenau Hosp. Res. Inst., Philadelphia, Pa.]

Female rats were maintained from the age of 6 weeks on a purified diet without cystine, methionine, choline or vitamin B_{12}. They were killed when they became ill, so that the tissues were obtained without autolysis. Vitamin B_{12} and fat were estimated in the liver. The average content of vitamin B_{12} was 0·03 μg. per g. dry liver, compared with 0·15 μg. for rats receiving the same diet supplemented with vitamin B_{12}. The fat content of the liver was abnormally high and lesions were apparent in it after 1 year on the diet and were severe after 2 years. Cirrhosis, cystic changes and cholangiofibrosis occurred in the liver without fatty changes. Structural changes resembling those preceding the neoplasms produced by *p*-dimethylaminobenzene were induced, and were delayed by addition of vitamin B_{12} to the diet.—A. M. Copping.

453

MIYAGAWA, K. [**Experimental studies on carbon disulfide poisoning. (Effects of l-methionine and l-methionine combined with V.B_{12} upon CS_2 poisoning.)**] *Shikoku Acta med.*, 1955, **6,** 1–6. [Dept. Physiol., Sch. Med., Tokushima Univ.] In Japanese: English summary.

FATTERPAKER, P., MARFATIA, U. and SREENIVASAN, A. **Protective action of vitamin B_{12} in the hyperthyroid rat.** *Nature*, 1955, **176,** 165. [Foods Sect., Dept. Chem. Technol., Univ. Bombay.]

Glutathione was estimated in the liver, adrenal glands and blood of rats having a basal diet with and without vitamin B_{12} or one containing iodinated casein with and without vitamin B_{12}. Glutathione was low in the tissues but high in the blood from hyperthyroid rats, and acetylating mechanisms were impaired. These effects of iodinated casein were prevented by adding vitamin B_{12} to the diet. The vitamin had no significant effect when added to the basal diet without iodinated casein.—A. M. Copping.

455

KLINE, I. T. **Relationship of vitamin B_{12} to stilbestrol stimulation of the chick oviduct.** *Endocrinology*, 1955, **57,** 120–128. [Dept. Obstet., Univ. Hosps., Cleveland, Ohio.]

When chicks from a stock depleted of vitamin B_{12} were kept on a diet deficient in the vitamin, their oviduct response to stilboestrol was significantly less than in chicks receiving vitamin B_{12}. The role of folic acid as a supplement to vitamin B_{12} and as inhibitor of the folic acid antagonist aminopterin was investigated. Addition of extra vitamin B_{12} did not increase the effect of folic acid in inhibiting aminopterin. Both vitamin B_{12} and folic acid were essential for the optimum response of the oviduct to stilboestrol. The interrelations of the two vitamins in this reaction are discussed.—A. M. Copping.

456

BURNS, M. J. and ACKERMAN, C. J. **Effect of dietary choline, methionine, and vit. B_{12} on weight and composition of eggs.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 420–421. [Dept. Animal Husb. Nutrit., Alabama Polytech. Inst., Auburn.]

Chicks were given for from 50 to 60 weeks a basal diet lacking choline, with or without supplements of methionine, choline or vitamin B_{12}. In hens receiving a methionine supplement, yolk size and choline content were increased by 40 and 70 per cent., respectively, but egg size was not affected. A supplement of 3 g. choline per kg.

diet increased egg size, yolk size and total choline content by 17, 59 and 97 per cent., respectively. Addition of 30 μg. vitamin B_{12} per kg. diet increased egg size, yolk size and total choline content by 21, 59 and 102 per cent., respectively. With the highest amount of methionine added, 10 g. per kg. diet, the percentage of fat in the yolk was 60·3; with supplements of vitamin B_{12} or choline it was 63 and 65·1, respectively, compared with 62 in yolks of commercial eggs.

NORDFELDT, S., KVARNBÄCK, S. and ALM, H. Utfodringsförsök med prokain-penicillin samt vitamin B_{12} till växande gödsvin. [**Feeding experiments with procaine penicillin and vitamin B_{12} for growing pigs.**] *Kungl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 108, 1954, pp. 10. English summary.

Three different experiments were made with a total of 230 pigs fed on rations with either vegetable or animal protein. In one experiment procaine penicillin at the rate of 20 g. per ton increased the growth rate of pigs fed on a ration containing oats, barley, wheat bran, soya bean oilmeal and other oilcakes by 9 per cent., a significant increase. Further supplementation with vitamin B_{12} at the rate of 13·5 mg. per ton had no additional effect. Supplements of penicillin did not produce as good growth as a ration of dried skimmed milk, fishmeal and meatmeal, but did produce a certain increase in growth when added to the animal-protein ration. In the other 2 experiments growth on a vegetable-protein ration supplemented with vitamin B_{12} was improved by the addition of penicillin at the rate of 5 g. per ton but was still inferior to that on the animal-protein ration. Feed consumption per kg. bodyweight increase tended to decrease when penicillin was used, particularly with the vegetable-protein ration.—A. Hepburn.

MOINUDDIN, M. and BENTLEY, O. G. **Microbiological versus biological vitamin B_{12} activity in bovine rumen liquor and feces.** *J. Nutrition*, 1955, **56,** 335–348. [Ohio Agric. Exp. Stat., Wooster.]

Microbiological tests with *Lactobacillus leichmannii* and biological tests with rats and chicks were made against graded doses of crystalline vitamin B_{12} on liquor from the rumen of a steer with a rumen fistula and on lyophilised extracts of dried faeces from the same animal. Weight gains and vitamin B_{12} in the liver and kidneys were the criteria of biological response. The microbiologically active vitamin B_{12} substances present in faeces were fully active for the rat, but only about 70 per cent. of the microbiological activity in the rumen liquor appeared to be available. Chicks failed to show a growth response to graded doses of crystalline vitamin B_{12}, but the extent of the increases in vitamin B_{12} in the liver and kidneys suggested that the microbiological activity of rumen liquor and faeces was not fully available for the chick.—A. M. Copping.

DAWBARN, M. C. and HINE, D. C. (with SMITH, J.) **The determination of vitamin B_{12}-activity in the organs and excreta of sheep. 3. The excretion of vitamin B_{12}-active factors in the faeces and urine of sheep.** *Austral. J. Exp. Biol. Med. Sci.*, 1955, **33,** 335–348. [Div. Biochem., C.S.I.R.O., Adelaide.]

For parts 1 and 2 see Absts. 4482, Vol. 24; 3595, Vol. 25.

Vitamin B_{12} activity was measured in faeces and urine by microbiological methods with *Bacterium coli* mutant, *Lactobacillus leichmannii* and *Ochromonas malhamensis*. The results obtained with *Bact. coli* were higher than with the other two organisms but by all the methods it was found that the vitamin B_{12} activity in the faeces was much greater in sheep given adequate cobalt than in those given cobalt-deficient rations. Little vitamin B_{12} was excreted in the urine but it too gave some measure of the animal's cobalt intake. When 500 μg. vitamin B_{12} was given daily by mouth to a sheep on a cobalt-deficient diet about 25 per cent. of the dose was excreted in the faeces and less than 0·3 μg. in the urine. If 50 μg. vitamin B_{12} was given parenterally daily 30 to 36 per cent. was excreted in the urine and some in the faeces also. In one sheep, 2 or more vitamin B_{12} factors were identified in the urine by differential microbiological tests and by ionophoresis.

KOVAL'SKIĬ, V. V. and RAETSKAYA, YU. I. Sintez vitamina B_{12} v organisme ovets pod vliyaniem kobal'ta i kal'tsiya v biogeokhimicheskoi provintsii bednoi kobal'tom. [**Synthesis of vitamin B_{12} in the sheep under the influence of cobalt and calcium in a cobalt-deficient biogeochemical region.**] *Dokl. Akad. Nauk. SSSR*, 1955, **100,** 1131–1134. [V.I. Vernadskii Inst. Geochem., Acad. Sci., SSSR.]

The livers of healthy sheep contained, per cent., from 18·6 to 21·7 μg. vitamin B_{12}, those of sheep with slight Co deficiency from 16 to 17·5 μg. and with more severe Co deficiency from 4 to 6·4 μg. Supplements of Co alone or with Cu and I salts increased the vitamin B_{12} content of the liver of deficient sheep. The livers of sheep given 4 mg. $CoCl_2$ daily contained 83 per cent. more vitamin B_{12} than those of sheep having a basal ration low in Co, and when 4 mg. $CoCl_2$ was given with 3 g. $CaCO_3$ daily the increase was 166 per cent.

The vitamin B_{12} content of the liver was not always related to the Co content. One sheep had traces of vitamin B_{12} in the liver and 6·4 μg. Co per cent., 3 others had almost no vitamin B_{12} and from 4·2 to 4·6 μg. Co per cent.

Only about 20 per cent. of the Co in the liver was in the form of vitamin B_{12}, even when large amounts of the vitamin were present.

KLINE, E. A., KASTELIC, J. and ASHTON, G. C. **The effect of vitamin B_{12}, cobalt and antibiotic feeding on the composition of pork tissue of 100-pound pigs.** *J. Nutrition*, 1955, **56,** 321–334. [Dept. Animal Husb., Iowa State Coll., Ames.]

With diets and general experimental procedures similar to those previously reported (Abst. 2027, Vol. 25), tests were made of the effect of adding vitamin B_{12} or cobalt to diets with or without antibiotic supplements for pigs up to 100 lb. liveweight. Measurements were made of thickness of back fat, percentage lean, weight of liver, kidney, spleen, bone and bone marrow, and breaking strength of bone in the femur. There was little consistent difference in fat or carcase quality with the several treatments. Inclusion of antibiotics in the ration did not affect the vitamin B_{12} content of the kidney, liver, spleen or muscle. Without antibiotics, inclusion of vitamin B_{12} in the ration increased the amount of the vitamin in the tissues and also the P content of the tissues. Addition of Co had no significant effect on tissue composition.

The results are discussed with those reported in Abst. 2027, Vol. 25, and are not considered to explain adequately the improved growth of young pigs receiving a diet lacking vitamin B_{12} but containing antibiotics.—A. M. Copping.

463

PEYNAUD, É. and LAFOURCADE, S. Sur la présence de vitamine B_{12} dans les vins. **[Presence of vitamin B_{12} in wine.]** *C.R. Acad. Sci.*, 1955, **241,** 127–129.

Small amounts of vitamin B_{12} activity as measured with *Bacterium coli* were found in crushed grapes and in red and white wines. The amounts ranged from 0 to 0·13 μg. per litre and, in general, the wines contained more than the grapes, which was evidence of some synthesis during fermentation.—A. M. Copping.

464

NEUJAHR, H. Y. **On vitamins in sewage sludge. 2. Formation of vitamin B_{12}-, folic acid-, and folinic acid factors in municipal sludge. 3. Vitamin B_{12} activity of different types of sewage sludge.** *Acta chem. scand.*, 1955, **9,** 622–630; 803–806. [Div. Food Chem., Royal Inst. Technol., Stockholm.]

2. In a previous study (Abst. 1850, Vol. 24) the presence of vitamin B_{12}, folic acid and folinic acid activity was demonstrated in municipal sludge. The process of formation of these substances during aerobic and anaerobic fermentation was investigated. It was found that some of the micro-organisms used cyanocobalamin and others produced it or factors related to it. At different stages of fermentation, cyanocobalamin, pseudovitamin B_{12} and factors A, B, C_1 and C_2 were identified by bio-autographic methods. It is suggested that complicated symbiotic and synergistic processes were concerned in the synthesis of vitamin B_{12} factors and also of folic and folinic acids; isolation of the organisms responsible for definite syntheses has not yet been achieved.

3. With microbiological and chromatographic methods of analysis vitamin B_{12} activity was studied in sewage sludge from 5 plants with different digestion processes. The amounts of vitamin B_{12} activity present were related to the nature of the incoming fresh solids and to the processes of aerobic or anaerobic digestion employed in treating the sludge. Higher values were found in sludge from a food factory than in ordinary municipal digested sludge. In one process 27 samples taken over a period of 3 years gave an average of 14 mg. vitamin B_{12} activity per kg. dry solids, with a range from 7 to 30 mg.

A. M. Copping.

465

JANSEN, B. C. P. and AUSSEN, B. S. **Trassi, a far-eastern source of cobalamin (vitamin B_{12}).** *Doc. Med. geogr. trop.*, 1955, **7,** 50–52. [Lab. Physiol. Chem., Univ. Amsterdam.]

The results of microbiological tests showed that vitamin B_{12} was present, even after 2 years' storage, in considerable amounts in *trassi*, which is a preparation of fermented shrimps or fish eaten by the indigenous population in Java. The amount of the vitamin present varied from 110 to 430 μg. per g. dry substance, but it was not possible to determine whether the concentration of vitamin

B_{12} changed during fermentation. The average daily intake was from 1 to 5 g. among the poorer people and from 5 to 10 g. among those better off; such amounts would probably cover the daily requirement.—L. Wills.

466

ROHATGI, K., BANERJEE, M. and BANERJEE, S. **Effect of germination on vitamin B_{12} values of pulses (leguminous seeds).** *J. Nutrition*, 1955, **56**, 403–408. [Dept. Physiol., Presidency Coll., Calcutta.]

For estimating vitamin B_{12} in pulses before and after germination, methods of extracting the vitamin were investigated. Trypsin digestion followed by autoclaving in the presence of cyanide gave the best results. *Lactobacillus leichmannii* was used as test organism. In seven varieties of Indian pulses, *Phaseolus mungo*, *P. radiatus*, *Lens esculenta*, *Pisum sativum*, *Lathyrus sativus*, *Cajanus indicus* and *Cicer arietinum*, the vitamin B_{12} content of the ungerminated seed ranged from 0·36 to 0·61 μg. per 100 g. Germination for 48 hr. caused a considerable increase and for 96 hr. up to a six-fold increase. The relation of the findings to the comparative rarity of pernicious anaemia among Indian vegetarians is discussed.—A. M. Copping.

OTHER B VITAMINS

467

GREENBERG, S. M. and ERSHOFF, B. H. **Comparative effects of liver residue and dietary fat on mineral oil toxicity in rats fed a low fat ration.** *Exp. Med. Surg.*, 1955, **13**, 143–155. [Emory W. Thurston Labs., Los Angeles, Calif.]

When immature rats were fed for 6 weeks on a purified low-fat diet containing 7·5 per cent. mineral oil, they grew less and had a higher mortality than rats on the same diet without mineral oil. They also developed alopecia, and some had the spastic gait and humped back characteristic of biotin deficiency. The replacement of sucrose by defatted, desiccated whole liver as 10 per cent. of the diet protected the animals. Several other supplements replacing equal amounts of sucrose were added to the diet or were given parenterally; B vitamins given orally alone or with liver extract given parenterally and biotin, or a liver concentrate, or casein had no significant protective action, but defatted liver residue, or cottonseed oil or hydrogenated coconut oil as 10 per cent. of the diet all had protective action. Cottonseed oil in doses as small as 20 or 100 mg. daily also had protective action but the same amounts of hydrogenated coconut oil had none. The results are discussed and it is suggested that the defatted, water-soluble fractions of liver contain a factor or factors distinct from any of the known nutrients which can replace dietary fat in counteracting the toxic effect of mineral oil on rats given a diet low in fat.—L. Wills.

VITAMIN C (ASCORBIC ACID)

468

SULLIVAN, M. X. and CLARKE, H. C. N. **A highly specific procedure for ascorbic acid.** *J. Assoc. Off. Agric. Chem.*, 1955, **38**, 514–518. [Georgetown Univ., Washington, D.C.]

The method is based on reduction of $FeCl_3$ by ascorbic acid at *p*H 1 to 2 and estimation of the resulting $FeCl_2$ with $\alpha\alpha'$-dipyridyl. Reductone was the only one of several reducing agents which interfered with the reaction and its interference was prevented with orthophosphoric acid. The method was applied to urine, orange juice and honey and the values were smaller than those obtained with the indophenol method.

UYAMA, Y. and OGINO, S. **Study on the metabolism of vitamin C in the crystalline lens. 1. Biological formation of ascorbic acid from hexose.**

UYAMA, Y., OGINO, S. and MISHIMA, K. **2. Biological formation of ascorbic acid from mannose in the bovine lens (biological observation on the basis of antiscorbutic activity).** *Med. J. Osaka Univ. (Engl. Ed.)*, 1955, **6**, 217–224; 225–228. [Dept. Ophthalmol., Med. Sch., Osaka Univ.]

1. Ascorbic acid was synthesised when an extract of rabbit crystalline lens was incubated with mannose or, to a less extent, with glucose. Fructose, galactose and ribose gave no synthesis. Synthesis took place mainly in the cortex of the lens and not in the cornea, ciliary body or retina. Ascorbic acid was readily synthesised by the bovine lens but only to a slight extent by the guineapig lens.

2. Injection of the reaction mixture of mannose and bovine lens prolonged the life of scorbutic guineapigs, proving the synthesis of ascorbic acid.

BURNS, J. J., MOSBACH, E. H., SCHULENBERG, S. and REICHENTHAL, J. **Studies on the incorporation of C^{14} administered as L-sorbose into L-ascorbic acid and D-glucose in rats.** *J. Biol. Chem.*, 1955, **214**, 507–514. [Res. Serv., Third (New York Univ.) Med. Div., Goldwater Mem. Hosp., New York.]

D-Glucose, L-sorbose uniformly labelled with ^{14}C and L-sorbose-6-^{14}C were injected into rats treated with chloretone. About 0·3 per cent. of the ^{14}C administered was isolated in each case from the urinary L-ascorbic acid. In the degradation products of ascorbic acid from rats receiving L-sorbose-6-^{14}C about half the radio-activity was distributed equally between carbon atoms 1 and 6, which was evidence that L-sorbose was converted to ascorbic acid only after cleavage of the carbon chain and was not, therefore, a direct precursor in the synthesis of ascorbic acid from glucose. L-Sorbose was extensively metabolised to CO_2 and was found to be converted to glucose of the liver glycogen after cleavage of the molecule.

A. Hepburn.

CHIU, Y. Y. **The effect of diet on the excretion of ascorbic acid in rabbit urine.** *Shikoku Acta Med.*, 1955, **6**, 259–261. [Sakuramachi Hosp. St. John the Evangelist, Tokyo.] Japanese summary.

Four rabbits were maintained for 11 days on a vitamin-C-deficient diet of bean-curd refuse, another rabbit having green feed in addition. The deprived animals were then given a daily injection of 20 mg. ascorbic acid for 9 days. There was no appreciable change in the volume of urine, and daily excretion of ascorbic acid rose only from about 1 to 2 mg. to 1·5 to 2·5 mg., from which it is concluded that the rabbit does not synthesise ascorbic acid to any great extent. None of the rabbits showed signs of scurvy.—J. S. Thomson.

472

CHALOPIN, H. Électrophorèse du sérum de cobaye scorbutique. **[Electrophoresis of the serum of scorbutic guineapigs.]** *C.R. Soc. Biol.*, 1955, **149**, 265–267.

On examination by paper electrophoresis, serum from scorbutic guineapigs showed several differences from normal serum. The albumin : globulin ratio was less by about 20 per cent. and the mobility of each fraction was below normal.

473

REHELL, B. and RÄIHÄ, C. E. **Influence of ascorbic acid deficiency on the adenosine triphosphate content of the blood.** *Ann. Paediat. Fenn.*, 1954–55, **1**, 78–81. [Child. Clin., Univ. Helsinki.]

Ascorbic acid decreased somewhat in whole blood from guineapigs fed for 4 weeks on a scorbutogenic diet, and the amount of adenosine triphosphate in the blood cells increased to about twice that normally found.—A. Hepburn.

474

TAKEDA, Y. and HARA, M. **Significance of ferrous ion and ascorbic acid in the operation of the tricarboxylic acid cycle.** *J. Biol. Chem.*, 1955, **214**, 657–670. [Dept. Nutrit., Sch. Med., Univ. Osaka, Japan.]

Liver mitochondria from guineapigs into which $\alpha\alpha'$-dipyridyl had been injected to make them iron-deficient, or which had been deprived of ascorbic acid, had less than the normal capacity to oxidise citrate. Aconitase activity also was low but it was restored, though only partly, in scorbutic guineapigs, by the addition of ferrous ion and ascorbic acid to the mitochondria. Urinary citric acid in both groups greatly increased after the administration of butyrate with malate or citrate. It was assumed that the primary lesion in ascorbic acid deficiency is loss of power to mobilise ferrous iron, from which follows the inactivation of the enzymes that require iron as a cofactor, such as homogentisicase and aconitase. The inactivation of aconitase interrupts the tricarboxylic acid cycle and hence disturbs metabolism.—A. Hepburn.

475

ROSSI, C. S. Rapporti fra vitamina 'C' e tributirrinasi epatica e pancreatica. **[Relation between vitamin C and tributyrinase in the liver and pancreas.]** *Sperimentale, Sez. Chim. biol.*, 1954, **5**, 11–17. [Ist. Chim. Biol., Univ. Padua.]

In the liver and pancreas of normal and scorbutic guineapigs, tributyrinase was estimated by measuring the amount of CO_2 liberated from Ringer bicarbonate solution by the action of butyric acid derived from tributyrin.

In the liver of deprived guineapigs [no numbers given] the mean tributyrinase activity fell up to about the 10th day, then rose until, about the 25th day, it had reached the original value. Addition of ascorbic acid *in vitro* had no consistent effect with normal liver tissue; it usually increased the activity of preparations from deprived animals.

In the pancreas, tributyrinase activity was not affected by deprivation of vitamin C. Results of adding ascorbic acid *in vitro* were not consistent.

It is concluded that in the guineapig the tributyrinase of the liver is distinct from that of the pancreas, and that vitamin C does not function as their coenzyme.—E. M. Hume.

476

LINO, A. and BARNARDINI, A. Attività lisozimica dei tessuti di animali carenti di acido ascorbico. [**Lysozyme activity of the tissues of animals deficient in ascorbic acid.**] *Boll. Soc. ital. Biol. sper.*, 1954, **30,** 1070–1073. [Ist. Patol., Univ. Catania.]

Guineapigs were given a scorbutogenic diet, 10 of them with, and 10 without, a daily addition of 750 μg. ascorbic acid. After 30 days they were killed, and ascorbic acid was estimated in the liver and adrenal glands, and lysozyme in the liver, spleen and lungs. No ascorbic acid could be detected in the tissues of the deprived animals, and the lysozyme content of all 3 tissues of the deprived was less than of the non-deprived guineapigs.—E. M. Hume.

477

RIDGE, J. W. **Sodium and chloride of the aqueous humour of normal and scorbutic guinea-pigs.** *Brit. J. Ophthalmol.*, 1955, **39,** 534–539. [Med. Res. Counc. Ophthalmol. Res. Unit, Inst. Ophthalmol., Univ. London.]

The ratio of the concentration of sodium in the aqueous humour to that in the plasma from normal guineapigs was found to be 1·04, a value considerably greater than that found in other animals and in agreement with the findings of Scholz (*Amer. J. Ophthalmol.*, 1953, **36,** No. 6, 64). When guineapigs were given a scorbutogenic diet until no ascorbic acid was detected in the aqueous humour and the guineapigs were in a sub-clinical state of scurvy there was no change in the ratio, which was found by Scholz to decrease in guineapigs with severe scurvy. Saturation with ascorbic acid had no effect. The normal ratio for chloride, 0·90, also was unaffected by scurvy or saturation with ascorbic acid.—A. Hepburn.

478

CASENTINI, S. L'acido pantotenico e la sua azione di risparmio sulle scorte tissutali di ac ascorbico nella cavia. [**Sparing action of pantothenic acid on the depletion of tissue ascorbic acid in guineapigs.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 1388–1390. [Ist. Farmacol., Univ. Milan.]

Ascorbic acid was estimated by the method of Roe and Kuether (Abst. 261, Vol. 13) in certain tissues of 12 male guineapigs weighing about 235 g., maintained on a constant diet. Six of them received daily for 10 days an intramuscular injection of 10 mg. Na pantothenate per 100 g. bodyweight. The mean ascorbic acid content of the tissues of those given pantothenate was higher than of those not given it by, per cent., liver 54, muscle 41, adrenal glands 18, spleen 18 and brain 11.—E. M. Hume.

479

SCALABRINO, R. and ROSSANDA, M. Effetto degli aminoacidi solforati (cisteina, cistina, metionina) sul contenuto in acido ascorbico dei tessuti del ratto. [**Effect of sulphur aminoacids (cysteine, cystine and methionine) on the ascorbic acid content of rat tissues.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 1372–1374. [2. Div. Med., Osp. Fatebenefratelli, Milan.]

Ascorbic acid was estimated by the method of Roe and Kuether (Abst. 261, Vol. 13) in the blood, liver and adrenal glands of 4 groups of 7 or 8 male rats weighing about 85 g. which had been maintained for 15 days on the diet of Randoin and Causeret (Abst. 3159, Vol. 17) with addition of 1 per cent. of cystine or cysteine or methionine or with no addition. There was no loss of weight or sign of intoxication. There was little difference between the groups in the amount of ascorbic acid in the blood or liver. In the adrenal glands the amount was slightly low in the groups given cystine or cysteine and, more definitely, high in those given methionine.—E. M. Hume.

480

LACHANCE, J. P. and PAGÉ, É. Effets de l'insuline et de la thyroxine sur la graisse brune interscapulaire et sur sa teneur en glycogène et en acide ascorbique. [**Effects of insulin and of thyroxine on the brown interscapular fat and on its content of glycogen and ascorbic acid.**] *Rev. canad. Biol.*, 1955, **14,** 74–88. [Dept. Physiol. Nutrit., Fac. Med., Laval Univ., Quebec.] English summary.

The weight of brown interscapular fat was measured in rats normally fed, or fasting for 18 hr. with or without a single dose of insulin. Fasting greatly reduced the weight of the brown fatty tissue. The loss was rapidly repaired after a dose of insulin. The glycogen content of the brown fat increased after insulin but the ascorbic acid content was not affected. Prolonged treatment with insulin had no significant effect on the weight, ascorbic acid or glycogen content of the brown fat.

Treatment with thyroid powder for 19 days caused an increase in the amount of brown interscapular fat and a complete disappearance of white perinephric fat. In the brown fat tissue there was an apparent decrease in the ascorbic acid content associated with the hypertrophy, but there was no significant decrease in the content of ascorbic acid or glycogen which could be attributed to the treatment with thyroxine.—A. M. Copping.

481

KERTAI, P. and LUDÁNY, G. Die vegetative Nerventätigkeit und der Ascorbinsäuregehalt des Blutplasma. 2. [**Activity of the vegetative nervous system and the ascorbic acid**

content of the blood plasma. 2.] *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1954, **6,** 379–390. [Patho-physiol. Inst., Med. Univ., Budapest.] English and French summaries.

Ascorbic acid was estimated by a modification of the method of Roe and Kuether (Abst. 261, Vol. 13). In dogs anaesthetised with Evipan, the ascorbic acid content of the blood rose within 15 min. after intravenous injection of adrenaline even when the vessels from the adrenal glands were tied. In 3 human subjects also, the ascorbic acid content of the blood rose after subcutaneous injection of adrenaline. In the dogs the blood sugar value rose and reached its maximum after the ascorbic acid value had begun to fall. The blood ascorbic acid value rose also after direct stimulation of the splanchnic nerve fibres (see Abst. 4669, Vol. 8), sympathetic stimulation by way of the carotid sinus, and intravenous injection of *dl*-noradrenaline. The ascorbic acid content of the blood in the veins from the adrenal glands did not rise on direct stimulation of the splanchnic nerve fibres, which caused it to rise in the blood in the femoral vein, nor was there loss of ascorbic acid from an adrenal gland after such stimulation, the other adrenal gland having been previously removed. Administration of insulin or pilocarpine or stimulation of the vagus nerve had no effect on the blood ascorbic acid value.

Oertel, G. and Hein, H. Ausscheidung von 17-Oxy-corticosteron im Harn skorbutischer Meerschweinchen. [**Excretion of 17-hydroxycorticosterone in the urine of scorbutic guinea-pigs.**] *Hoppe-Seyler's Ztschr.*, 1955, **301,** 191–193. [Lab. Firma Byk-Gulden-Lomberg, Chem. Fabrik G.m.b.H., Constance.]

In continuation of previous work (Abst. 5007, Vol. 25) 17-hydroxycorticosterone was isolated from the pooled 24-hr. urine of 24 guineapigs and estimated by paper chromatography. After 7 days of a normal diet the amount found was 7 μg. per animal; after 8 days of a vitamin-C-free diet of autoclaved roots, 53 μg. Since the concentration of 17-hydroxycorticosteroids in the blood of scorbutic guineapigs is high also (Abst. 1872, Vol. 24), the amount produced must be considerably increased. Physiological implications will be discussed elsewhere.—W. M. Deans.

483

Harris, L. J., Constable, B. J., Hughes, R. E. and Loewi, G. **Influence of cortisone on ascorbic-acid requirements of guinea-pigs: an assessment by the tooth-structure method.** *Brit. J. Nutrition*, 1955, **9,** 310–316. [Dunn Nutrit. Lab., Univ. Cambridge.]

Six groups of 12 guineapigs were fed for 14 days on a diet with 0, 0·5, 1·0, 2·0 or 4·0 mg. ascorbic acid daily. Another group received 15 g. cabbage daily. Half of each group received 7·5 mg. cortisone daily by intramuscular injection. Although cortisone caused a relative decrease in the content of ascorbic acid in the adrenal glands it did not affect the degree of protection from ascorbic acid deficiency as assessed by the dental histology method.—A. Hepburn.

Krankenanst., Mannheim.]

For part 6 see Abst. 4559, Vol. 24.

Mitochondria were isolated from fresh pig adrenal glands by a method described. Fresh adrenal tissue contained from 200 to 300 mg. per cent. of ascorbic and dehydroascorbic acids, but the mitochondria contained at most 2 or 3 mg. per cent., which may have been due to imperfect isolation. The mitochondria were suspended in ice-cold Krebs Ringer solution at *p*H 6·5 and the proportions of diphosphopyridine nucleotide and dihydrodiphosphopyridine nucleotide were studied photometrically.

The removal of hydrogen from added dihydrodiphosphopyridine nucleotide was activated by cytochrome *c* but less readily than by ascorbic acid, which was most effective at *p*H 6·5. Dehydroascorbic acid could not replace ascorbic acid as hydrogen acceptor in this system.—D. Duncan.

Milković, S. **Influence of vitamin C on non-adrenal-mediated action of ACTH in castrated DOCA treated rats.** *Arch. internat. Physiol.*, 1955, **63,** 238–240. [Dept. Pharmacol., Med. Fac., Univ. Zagreb.]

In castrated rats given injections of deoxycorticosterone acetate daily for 3 weeks, with adrenocorticotropic hormone and sodium ascorbate also for the last week, there was a significant decrease in the weight of the adrenal and thymus glands. The preputial glands showed significant hypertrophy. When ascorbate was replaced by

bicarbonate the adrenal gland weights increased slightly, thymus weights remained low and there was no significant hypertrophy of the preputial glands.—A. Hepburn.

487

BOOKER, W. M., TUREMAN, J. R., DACOSTA, F. M., POULSON, J. and MITCHELL, S. Q. **Relationship between glutathione and ascorbic acid in adrenocortical function.** *Amer. J. Physiol.*, 1955, **181,** 371–374. [Dept. Pharmacol., Sch. Med., Howard Univ., Washington, D.C.]

The ascorbic acid content of the whole body of intact and adrenalectomised mice exposed and not exposed to cold stress was about the same. Ascorbic acid decreased significantly after stress in intact mice treated with ascorbic acid or glutathione. Glutathione in doses of from 0·25 to 14 mg. per 25 g. bodyweight prolonged the survival of intact mice, and to a less extent of adrenalectomised mice, exposed to cold stress. In the latter small doses were often more effective than large.

Ascorbic acid in the adrenal glands of rats exposed to cold stress decreased but returned to normal after 12 hr. Cortisone prevented the decline of ascorbic acid but not of cholesterol.

A. Hepburn.

DUGAL, L. P., DESMARAIS, A. and GAGNON, P. M. **Influence of exposure to cold and ascorbic acid administration on the weight and the metabolic activity of the adrenal gland of hypophysectomized rats given ACTH.** *Canad. J. Biochem. Physiol.*, 1955, **33,** 677–680. [Dept. Exp. Physiol., Fac. Med., Laval Univ., Quebec.]

The left adrenal gland was removed from 178 hypophysectomised male rats, of which 94 were then exposed to a temperature of 14° ± 2° C. and the rest were kept at room temperature, 22° C. All received adrenocorticotropic hormone daily, and 6 days later the right adrenal gland was removed. Cold stress significantly increased the weight and succinic dehydrogenase activity of the adrenal glands and decreased the weight of the thymus. In a similar experiment the groups were divided and, during exposure to the 2 temperatures, were given sodium ascorbate or $NaHCO_3$. Ascorbate increased the response of the adrenal glands to the hormone at both temperatures, and cold stress produced no additional effect.

A. Hepburn.

BRAUN, H. Die Ascorbinsäure in Rattennebennieren, ihr Verhalten nach Applikation pharmakologisch wirksamer Substanzen und ihre Beziehung zur Corticosteroidsekretion und zur Entzündungshemmung. [**Ascorbic acid in the adrenal glands of the rat; its behaviour after administration of pharmacologically active substances and its relation to corticosteroid secretion and prevention of inflammation.**] *Arch. internat. Pharmacodyn.*, 1955, **101,** 381–397. [Pharmakol. Inst., Univ. des Saarlandes, Homburg.]

Ascorbic acid, estimated by the method of Roe and Kuether (Abst. 261, Vol. 13) in the adrenal glands of rats, decreased after all the substances injected except cortisone acetate, which caused an increase. The decrease was greatest after adrenocorticotropic hormone.—E. M. Hume.

491

MÖRSDORF, K. Zur Beeinflussung der Ascorbinsäureverteilung durch Antiphlogistica. [**The effect of anti-inflammatory agents on the distribution of ascorbic acid.**] *Arch. internat. Pharmacodyn.*, 1955, **102,** 249–265. [Pharmakol. Inst., Univ. des Saarlandes, Homburg.]

Ascorbic acid was estimated by the method of Roe and Kuether (Abst. 261, Vol. 13) in the adrenal glands, heart, liver, lungs, spleen and kidneys of groups of 16 male rats weighing about 150 g., killed from 120 to 150 min. after subcutaneous injection of one of the test substances. Normal values were established with 60 untreated animals. The substances tested were adrenocorticotropic hormone, cortisone, aminopyrin, phenazone, phenylbutazone, butapyrin, Na salicylate, acetylsalicylic acid, *p*-aminosalicylic acid, formalin, carbon tetrachloride and diphtheria toxin. All of them reduced the ascorbic acid content of the adrenal glands except cortisone, which left it unaffected. On the other organs the different substances had no constant effect, and no evidence emerged that the disappearance of ascorbic acid from the adrenal glands brought about an emission from them of hormones of the cortisone type antagonistic to inflammatory processes.—E. M. Hume.

NARPOZZI, A. and ROSSI, F. Potere complementare ed edema da albume d'ovo. [**Complement titre and oedema caused by egg albumin.**]

ROSSI, F. and NARPOZZI, A. Acido ascorbico ed edema da albume d'ovo nel ratto surrenalectomizzato. [**Ascorbic acid and oedema caused by egg albumin in adrenalectomised rats.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 1163–1165; 1165–1168. [Ist. Patol., Univ. Padua.]

Serum complement was estimated in 18 rats weighing about 200 g., maintained on a normal diet, before, and 30, 80 and 360 min. after peritoneal injection of 1 ml. fresh egg white. Oedema had not appeared after 30 min., was at its peak after 80 min., and was still evident after 360 min. The complement value had begun to fall already after 30 min., was much lower after 80 min., and was beginning to recover after 360 min.

In a similar experiment with 28 rats, a dose of 200, 300 or 450 mg. ascorbic acid per 100 g. bodyweight was given from 20 to 30 min. before the injection with egg white. With 450 mg. the appearance of oedema was inhibited or greatly retarded in comparison with rats not given ascorbic acid. With the smaller amounts there was retardation. The experiment was repeated with 19 rats from which the adrenal glands had been removed 2 days previously. In the rats not given ascorbic acid, the reaction to egg white was very severe and 2 died. When ascorbic acid was given the reaction was retarded and somewhat less severe, but several animals died.—E. M. Hume.

493

MURNEEK, A. E., MAHARG, L. and WITTWER, S. H. **Ascorbic acid (vitamin C) content of tomatoes and apples.** *Univ. Missouri Agric. Exp. Stat. Res. Bull.* No. 568, October 1954, pp. 24.

Ascorbic acid was estimated by the method of Bessey and King (Abst. 4168, Vol. 3). Dehydroascorbic acid was not estimated. The ascorbic acid content of tomatoes was greatly influenced by light, and increased in tomatoes grown in a greenhouse or outdoors after a few days of sunshine. Shaded tomatoes contained less than exposed fruit and the shaded halves of tomatoes contained least ascorbic acid. Greenhouse tomatoes grown during winter and spring usually contained less than tomatoes grown outside during summer and autumn, chiefly because of the lower light intensity. The content in field tomatoes increased from early to late summer. Mature (green) greenhouse tomatoes contained less ascorbic acid than ripe tomatoes but the comparatively high content of field tomatoes might decrease on ripening, especially if the temperature was high. The same decrease occurred in tomatoes ripened off the vine at a high temperature. In greenhouse tomatoes ripened off the vine at a relatively low room temperature ascorbic acid increased. An increase of soil N usually caused a decrease in ascorbic acid content. Growth hormone sprays did not seem to have any effect.

The ascorbic acid content of apples differed according to the variety, and was highest in Winesap. Summer apples generally contained more than autumn varieties. The content increased as maturing progressed, then decreased, except in summer apples and in Winesap where there was only a decrease during maturation. The last was the only variety which did not rapidly lose ascorbic acid on storage at from 70° to 80° F. Even at from 35° to 45° F. there was, in general, rapid loss during the first 2 weeks. Heavy N fertilisation of the soil reduced the ascorbic acid content, which was therefore greater in apples from weak than from strong trees. Apples on well exposed outside branches contained more ascorbic acid than on shaded branches, and the exposed halves of apples contained more than the shaded. Up to half the ascorbic acid content could be removed by peeling and much was destroyed on cooking especially in autumn apples. When cut or pulped, apples and tomatoes rapidly lost ascorbic acid on exposure to air.—A. Hepburn.

494

HOPP, R. and LAMDEN, M. P. **Ascorbic acid content of some Vermont-grown fruits and vegetables.** *Univ. Vermont Agric. Exp. Stat. Bull.* No. 579, May 1955, pp. 26.

By a method adapted primarily from that of Roe and Oesterling (Abst. 1225, Vol. 14) ascorbic acid was estimated over a 4-year period in a number of fruits and vegetables grown in Vermont. The yearly averages were not always from the same number of analyses, nor were the same varieties always used. The existence of varietal differences was confirmed. Ascorbic acid content was greatest in crops grown under their most suitable climatic conditions. Crops that do best in cool conditions, blueberries, raspberries, strawberries, broccoli, cabbage, peas, spinach and beans, had higher values for ascorbic acid than those given in the U.S. Dept. Agric. Handbook (Abst. 4782, Vol. 20); warm-weather crops like melons, peppers, summer squash and tomatoes were near to or below the standard values.—A. Hepburn.

495

LU, Y. C. and CHOU, Y. C. **The vitamin C content of winter vegetables and fruits in Ch'angsha.** *Chinese Med. J.*, 1955, **73,** 206–213. [Dept. Biochem., Hunan Med. Coll., Ch'angsha.]

After extraction with oxalic acid, ascorbic acid and dehydroascorbic acid were estimated by the 2 : 4-diphenylhydrazine method of Roe and Oesterling (Abst. 1225, Vol. 14), as modified by Penney and Zilva (*Biochem. J.*, 1945, **39,** 392), in 26 common kinds of fruits and vegetables, freshly purchased in the market in the winter of 1954. Oranges were gathered from the trees. Ascorbic acid and dehydroascorbic acid added to some of the foods were well recovered. The values are tabulated with the Chinese, English and Latin names of the plants.

In general, more than 10 per cent. of the vitamin C activity was present as dehydroascorbic acid ; the percentage ranged from 2·5 in long red peppers to 87·2 in yams, and was highest in material that had been stored before marketing. Graphs show the rate of decrease of ascorbic acid and of increase of dehydroascorbic acid in Ch'angsha oranges stored for 4 weeks at 0° C. and at room temperature (5° to 18° C.). The accumulation of dehydroscorbic acid at 0° C. is particularly noticeable. The best sources of vitamin C were peppers (*Capsicum*), mustard leaves, Hengyang orange and Hungkiang pomelo with values, in mg. total ascorbic acid per 100 g. fresh tissue, ranging from 77·5 to 240·6. Other good sources were purple colza (*Brassica campestris*, L., var.) shoots, garlic, spinach, fresh mustard root, onion, lotus root and celery with values from 37·5 to 66·5. Those available in the winter are considered to provide an adequate supply of vitamin C for the people.

E. M. Hume.

496

Fisher, K. H. and Dodds, M. L. **Reduced and total ascorbic acid values of thirty-four foods.** *Food Res.*, 1955, **20,** 247–249. [Coll. Home Econ., Pennsylvania State Univ.]

The foods analysed were canned fruits, cooked meat and fish, fresh, frozen and canned vegetables, milk and ice-cream. The amount of total ascorbic acid was slightly higher than of reduced ascorbic acid in most of the foods and was much higher in frozen asparagus and canned orange juice.

A. Hepburn.

OTHER VITAMINS

497

Géro, É. Stabilisation de l'acide déhydro-ascorbique par le pyrocatéchol. [**Stabilisation of dehydroascorbic acid with pyrocatechol.**] *C.R. Acad. Sci.*, 1955, **240,** 2176–2178.

The irreversible oxidation of dehydroascorbic acid in air was considerably reduced by the presence of pyrocatechol. It is suggested that pyrocatechol or a similar compound may be the active constituent of substances possessing vitamin P activity.—A. Hepburn.

498

Fuhrman, F. A. **Influence of dietary flavonoids on frostbite in the rat.** *Amer. J. Physiol.*, 1955, **181,** 123–127. [Dept. Physiol., Sch. Med., Stanford Univ., Stanford, Calif.]

In rats tissue loss caused by experimental frostbite of the feet was less when vitamin P as hesperidin methyl chalcone or calcium flavonate glucoside from lemon was added to a purified diet. The protective effect of flavonoids was greater on mild than on severe frostbite. Arrest of blood flow in response to adrenaline in the terminal vascular bed of the rat meso-appendix was more rapid in rats given flavonoids than in those given a flavonoid-free diet. It is suggested that flavonoids prevent rapid loss of fluid through the capillary walls in the injured tissue and possibly prevent stasis, which is one of the dangers of cold injury.

Chiancone, F. M., Ginoulhiac, E., Mainardi, L., Tenconi, L. T. and Lamanna, A. Acido orotico : studio general ed osservazioni sperimentali come fattore di crescita nel ratto. [**Orotic acid as a growth factor for rats: a general study and experimental observations.**]

Acta vitaminol., 1955, **9**, 101–120. [Lab. Direzione Med. Centrale, Lepetit S.p.A., Milan.] French, English, German and Spanish summaries.

When 2 groups of 20 rats weighing about 60 g. were fed on a purified diet, complete except for vitamin E, and one group was given daily for 6 weeks an addition of 186 mg. K orotate per kg. diet, there was no difference in growth rate between the groups. When groups of 10 rats were given the same diets with only 7 per cent. protein and with vitamin E, there was again no difference in growth rate.

Other comparisons were made with the diets with and without orotate. When the diet lacked the whole vitamin B complex, loss of weight began a little later and was slightly less severe in the rats given orotate. When the whole vitamin B complex was then given to the same rats, recovery of weight was more rapid with orotate than without. When vitamin B_1 or pyridoxine was thus given instead of the whole complex there was no difference between the groups. In rats deprived of vitamin B_6, orotate in no way mitigated the effects of the deprivation. In rats starved for 10 days and then given a diet high or low in protein, administration of orotate had no effect on the rate of recovery. Of rats given sulphaguanidine and deprived of vitamin B_{12} and folic acid, fewer died when orotate was given. When sulphaguanidine was withdrawn, addition of orotate or folic acid and vitamin B_{12} brought about weight increase; addition of all 3 had the best effect. Orotate had no power to potentiate a synthetic oestrogen or to replace folic acid in counteracting the effect of aminopterin.—E. M. Hume.

Pitan.*, 1955, **14**, No. 3, 22–26. [Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

Young rats in 4 groups were given a standard diet containing 18 per cent. protein, a similar diet containing only 10·7 per cent. protein and more carbohydrate, or a diet containing 18 per cent. protein but deficient in tryptophan or histidine. After from 1 to 60 days blood catalase and peroxidase were estimated at 20° C. and after heating to a temperature just below that normally required to inactivate the enzymes.

N.A. and R., January 1956

The samples from the first group showed progressively reduced enzyme activity after heating. In the second group this effect was much greater for catalase, but was of the same order for peroxidase. The rats on the tryptophan- and histidine-deficient diets gave low values for both enzymes at both temperatures.—D. W. Taylor.

MAGEE, D. F. and ANDERSON, E. G. **Changes in pancreatic enzymes brought about by alteration in the nature of the dietary protein.** *Amer. J. Physiol.*, 1955, **181,** 79–82. [Dept. Pharmacol., Sch. Med., Univ. Washington, Seattle.]

Estimations were made of the trypsin and lipase contents of dried pancreas from rats given synthetic diets. Of 4 groups each of 10 animals 3 had mixtures rich in protein, with 30 per cent. casein, gelatine or zein and 1 had the same diet with only 5 per cent. casein and 25 per cent. glucose. For the whole pancreas the contents of both enzymes were greater in the casein than in the 3 other groups, which were comparable with each other. When expressed per 100 mg. tissue the same was true for the trypsin, but for lipase the value for the casein groups was significantly greater only in comparison with the low-protein group.

To test the hypothesis that the pancreas may secrete the enzymes only if stimulated to do so by pancreozymin produced in adequate amount by the duodenum, a second experiment was made. Of 3 groups of 10 rats each, 2 were given similar diets with 8 per cent. casein without and with daily subcutaneous injections of 400 μg. urethane of β-methylcholine chloride (Urecholine), a pancreatic stimulant, and the third had 7 per cent. casein and 1 per cent. *dl*-valine. The mean content of each enzyme was significantly higher in both the Urecholine and the valine groups than in the casein group, expressed on either basis.

It is concluded that for enzyme production by the pancreas of the rat an adequate stimulus for the release of pancreozymin is of greater importance than is the quality of the protein in the diet, and that *dl*-valine is potent in stimulating this function of the duodenum.—D. Harvey.

511

MATTSON, F. H. and BECK, L. W. **The digestion *in vitro* of triglycerides by pancreatic lipase.** *J. Biol. Chem.*, 1955, **214,** 115–125. [Res. Div., Procter and Gamble Co., Cincinnati, Ohio.]

The hydrolysis of low-melting glycerides of cottonseed oil by pancreatic lipase was promoted by a high electrolyte concentration of 1 to 2 *M* and by low concentrations of bile salts; higher levels of bile salts were inhibitory. Hydrolysis allowed to proceed for less than 1 hr. produced appreciable amounts of 2-monoglyceride in addition to 1-monoglycerides. When 2-oleoyl dipalmitin was used as substrate, the diglyceride formed was oleoyl palmitin and the monoglyceride was mono-olein. Thus the hydrolysis of triglycerides *in vitro* appears to follow the same path as that *in vivo*, namely: triglyceride → 1 : 2-diglyceride → 2-monoglyceride. It is suggested that the enzyme lipase is specific for esterified primary alcohol groups.

BONDI, A. and BIRK, Y. **Studies on the action of papain on protein feeds.** *Bull. Res. Counc. Israel*, 1954, **4**, 57–62. [Agric. Res. Stat., Rehovoth.]

The rate of liberation of COOH, NH_2 and α-amino groups was measured when fat-free samples of 4 feedingstuffs were digested for 24 hr. at *p*H 5·0 and 7·5 with papain, either unactivated or activated with HCN. With activated enzyme liberation of COOH and NH_2 was greater at *p*H 5·0 than at *p*H 7·5; with unactivated enzyme the opposite was, in general, true. The feeds, in descending order of the extent to which they were digested, were groundnut cake, soya bean cake, fishmeal and meatmeal. Digests by papain when treated with trichloroacetic acid showed the same difference with origin as was found for pancreatic digests (see Abst. 1779, Vol. 23). From calculations of the average number of amino-acids in the peptide molecules in the digests it is shown that at *p*H 5·0 activation was without effect; at *p*H 7·5 the average number of amino-acids was lower with the activated than with the unactivated enzyme.

It is concluded that at *p*H 7·5 activation of the enzyme causes breakdown to peptides of smaller molecules and that the findings support the view (Willstaetter and Grassmann, *Hoppe-Seyler's Ztschr.*, 1924, **138**, 184) that activated and unactivated papain are two different enzymes.

STUNKARD, A. J., VAN ITALLIE, T. B. and REIS, B. B. **The mechanism of satiety: effect of glucagon on gastric hunger contractions in man.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 258–261. [Dept. Med., New York Hosp.]

Gastric motility was recorded in 7 healthy adults in the fasting state. In 16 experiments when glucagon was given intravenously in doses of from 0·125 to 4·0 mg., hunger contractions were abolished within 3 min. after the start of injection. The sensation of hunger disappeared or grew less. Saline had no such effect. After injection of glucagon the venous and capillary blood sugar rose rapidly to a peak in about half an hour. Falling blood sugar was accompanied by return of gastric hunger contractions and the sensation of hunger.—D. Duncan.

GREENBERG, L. A. and TURNER, J. M. **Effect of carbonated water on gastric acid secretion.** *New Engl. J. Med.*, 1955, **253**, 105–106. [Lab. Appl. Physiol., Yale Univ., New Haven, Conn.]

Ten healthy men in the post-absorptive state were given 400 ml. of a pectin test meal followed immediately on one occasion by 200 ml. water and on another by the same volume of carbonated water. At intervals the total stomach contents were removed, the volume was measured and, after samples had been taken for analysis by the technique of Hunt and Spurrell (Titles 2009, 2010, Vol. 21), the remainder was returned to the stomach The means for the amounts in mg. of HCl secreted in 15-min. periods after ingestion of the meal were with water 210, 216, 120 and 42 and with carbonated water 207, 132, 24 and 7.

The more rapid than normal emptying of the stomach which is caused by the carbonated water had the effect of reducing the mass of material eliciting secretion of acid. Carbonated water may, through this effect, be of use in counteracting retention of food and resulting hyperacidity in the stomach.—D. Harvey.

BELL, F. R. and LAWN, A. M. **Localization of regions in the medulla oblongata of sheep associated with rumination.** *J. Physiol.*, 1955, **128**, 577–592. [Dept. Physiol., Royal Vet. Coll., London, N.W.1.]

The medulla oblongata of sheep was explored with a stereotaxic instrument to obtain responses in the reticulo-rumen and the oesophagus. Stimulation of the area 6 mm. oral and 2 mm. caudal to the obex in the lateral region of the medulla caused responses in the rumen, and a similar but less well defined area elicited responses in the oesophagus. Many of the areas stimulated, when studied histologically, were seen to be in the lateral reticular formation, although many were closely adjacent to the nucleus ambiguus.

No intramedullary decussation occurred; each vagus nerve appeared to be related only to its own side of the medulla in this area.—A. T. Phillipson.

526

DZIUK, H. E. and SELLERS, A. F. **Physiological studies of the vagal nerve supply to the bovine stomach. 1. Comparison of responses in milk-fed and roughage-fed calves, using a chronic intrathoracic vagal electrode technique.** *Amer. J. Vet. Res.*, 1955, **16**, 411–417. [Div. Vet. Physiol., Sch. Vet. Med., Univ. Minnesota, St. Paul.]

Permanent electrodes were applied to the thoracic dorsal and ventral vagal nerves of calves. The pressure-recording devices were placed in the rumen by passing a long catheter through the nose to the stomach. Patterns of motility were recorded from strain-gauge transducers. Calves fed on roughage had more regular and stronger contractions than those of milk-fed calves, and responses to vagal stimulation were greater. Histological examination of the vagal fibres *post mortem* showed no gross deterioration due to the presence of the electrodes.—A. T. Phillipson.

527

LENGEMANN, F. W. and ALLEN, N. N. **The development of rumen function in the dairy calf. 1. Some characteristics of the rumen contents of cattle of various ages.** *J. Dairy Sci.*, 1955, **38**, 651–656. [Dept. Dairy Husb., Univ. Wisconsin, Madison.]

The rumen contents of calves, 1, 2, 3, 6 and 12 months old were examined and compared with those of adult animals for the short-chain fatty acids present, the speed with which the contents would digest cotton thread, the gas produced from " Solka Floc " and the numbers of protozoa and bacteria present.

In the fatty acids the only appreciable difference was less acetic acid in the calves 1 month old and a larger proportion of acids designated the " succinic-lactic " group. Counts of protozoa and bacteria showed large variations; it is clear that protozoa were absent or present in very small numbers in the animals 1 month old.

A. T. Phillipson.

528

DOUGHERTY, R. W. and MEREDITH, C. D. **Cinefluorographic studies of the ruminant stomach and of eructation.** *Amer. J. Vet. Res.*, 1955, **16**, 96–100. [Dept. Physiol., New York State Vet. Coll., Cornell Univ., Ithaca.]

The movements of the oesophagus, reticulum and rumen were studied by cineradiography in sheep during the introduction of a mixture of CO_2 and methane into the rumen. A barium meal was given so that the organs were well outlined.

An area of the thoracic oesophagus about 1½ in. from the diaphragm appears to act as a sphincter. The reticulo-ruminal fold can effectively hold back the material in the rumen from flowing into the reticulum. Gas is pushed into the reticulum by contraction of the dorsal sac of the rumen. The sequence of events during eructation is described.

A. T. Phillipson.

529

GRAU, H. Zur Funktion der Vormägen, besonders des Netzmagens. der Wiederkäuer. [**The function of the fore-stomachs of ruminants, especially the reticulum.**] *Berl. Münch. tierärztl. Wochenschr.*, 1955, **68,** 271–275. [Tieranat. Inst., Univ. Munich.] English summary.

This is a discussion of the literature on the structure and movements of the fore-stomachs, with some original observations. The hypothesis is advanced that well digested food with a higher sp. gr. accumulates at the bottom of the reticulum and that at the beginning of the reticulum contraction the lighter material is returned to the rumen, whereas at the end of the contraction the heavier material is tipped into the omasum. The reticulum is thus given the function of a "separating-stomach".—D. Duncan.

530

PALOHEIMO, L., MÄKELÄ, A. and SALO, M. L. **Some quantitative data on the role of the ruminant proventriculi in the digestion and absorption of nitrogen-free organic matter.** *Maataloust. Aikakausk.*, 1955, **27,** 70–76. [Dept. Animal Husb., Univ. Helsinki.] Finnish summary.

The digestibility of N-free organic matter and N-free non-lignin organic matter was estimated in the contents of the fore-stomachs and in the whole digestive tract of 14 cows and 5 young bulls after slaughter, with lignin as reference material. The animals were fed on hay three times a day for 10 days before slaughter. The mean digestibility of the N-free non-lignin organic matter was 86 per cent., range 76 to 99, for the fore-stomachs and 92 per cent. for the whole tract. It is concluded that the carbohydrates of hay are digested mainly before the feed reaches the abomasum and the products are directly absorbed into the blood or eructated as gases.—A. T. Phillipson.

531

AMMERMAN, C. B. and THOMAS, W. E. **Relative pH values and buffering capacities of the ruminal ingesta of lambs as affected by various forages.** *Cornell Vet.*, 1955, **45,** 443–450. [Kentucky Agric. Exp. Stat., Lexington.]

The *p*H of the rumen contents of 3 sheep was measured by a glass electrode and calomel electrodes inserted directly into the rumen. On alfalfa, ladino and bluegrass pastures the ranges of values were similar, except that the readings obtained while the sheep grazed bluegrass were about 0·2 unit higher than those from the other 2 pastures. Nearly all values lay between 6·0 and 6·5. With hay from the pastures all values were above this range.

There was little difference between the buffering capacities of the rumen liquors with the different forages.—A. T. Phillipson.

532

CARROLL, E. J. and HUNGATE, R. E. **Formate dissimilation and methane production in bovine rumen contents.** *Arch. Biochem. Biophys.*, 1955, **56,** 525–536. [Dept. Bacteriol., State Coll. Washington, Pullman.]

From the production of CO_2 from formate labelled with ^{14}C by rumen organisms and the relation between formate breakdown and methane production it is concluded that methane is produced at a rate compatible with the assumption that the hydrogen of formate is used to reduce CO_2. The rate of reduction of CO_2 by hydrogen is greater than the rate of decomposition of formate in the rumen under normal conditions, so that no hydrogen accumulates. There is some evidence that other substrates also are concerned with methane production.—A. T. Phillipson.

533

SHORLAND, F. B., WEENINK, R. O. and JOHNS, A. T. **Effect of the rumen on dietary fat.** *Nature*, 1955, **175,** 1129–1130. [Fats Res. Lab., Wellington.]

Lipids present in the rumen contents of sheep contained much more saturated fatty acid, especially stearic, than is present in pasture lipids, indicating that feed fat can be hydrogenated in the rumen. This hydrogenation was demonstrated *in vitro* by incubation, under CO_2, of linolenic acid with rumen contents for 3 days at 37° C. Analysis of the lipids of the rumen contents before and after incubation with linolenic acid showed that the tri-unsaturated acid was reduced to conjugated diene and further to the mono-ene stage and finally to stearic acid. *Trans* fatty acids were also detected after incubation. These findings explain the relative constancy of composition of ruminant depot fat in spite of differences in the nature of the dietary lipids.—G. A. Garton.

534

PARSONS, A. R., NEUMANN, A. L., WHITEHAIR, C. K. and SAMPSON, J. **Isolated gut and rumen motility as affected by extracts from bloat producing forages.** *J. Animal Sci.*, 1955, **14,** 403–411. [Dept. Animal Sci., Univ. Illinois, Urbana.]

Extracts of clovers, with the exception of red clover, were found to inhibit motility in the isolated intestine of the rabbit. Rumen contents from normal animals had little or no effect, but a sample from a cow dying of bloat was inhibitory. An extract of ladino clover known to cause bloat inhibited eructation, but not rumen movement.

A. T. Phillipson.

535

KHALILOV, F. K sravnitel'noi morfologii kishechnika mlekopitàyushchikh v svyazi s kharakterom pitaniya. [**The comparative morphology of the intestine of mammals in relation to the character of the feed.**] *Zool. Zh.*, 1955, **34**, 415–426. [Dept. Vertebrate Zool., Kazakh State Univ.]

Insectivores and carnivores were found to have the shortest intestines among mammals, herbivores, especially rodents and hoofed animals, the longest. Insectivores have no caecum and the large intestine is little developed. In carnivores the caecum is either absent or little developed. Most carnivores have a short large intestine and a long small intestine, but in carnivores which eat plant food as well as meat, such as dogs and badgers, the large intestine is longer than in those which eat only meat. In rodents there is a well developed large intestine and a somewhat less well developed small intestine. Ruminants have the longest intestine of the hoofed animals, solid-hoofed animals have the shortest, with pigs occupying an intermediate position.

The microscopic structure of the mucous membrane also shows differences. The villi are well developed in insectivores and carnivores. It is concluded that during the evolution of mammals an increase in the absorption surface of the intestine developed by increase in the length of the intestine in hoofed animals and by differentiation of intestinal villi with a short intestine in carnivores. In hoofed animals the intestinal villi are shorter and broader. An inverse correlation exists between the height of the villi and the length of the intestine. Horses have a shorter intestine and higher villi (420 μ. in the jejunum) than sheep and cows. The villi are weakly developed in rodents and particularly so in hoofed animals.

Intestinal crypts, judged by the thickness of the layer and the density of spacing, are also better developed in insectivores and carnivores. In rodents and hoofed animals, particularly the latter, the crypts have no considerable depth and are spaced thinly. It is possible to establish an inverse ratio between the development of intestinal crypts and the length of the intestine.

The muscularis mucosae is better developed in insectivores, carnivores and hoofed animals than in rodents. The thickness of the circular muscular layer is greater than that of the longitudinal layer throughout the intestine in carnivores and hoofed animals. Rodents have an equal thickness of the muscular layer in the duodenum and jejunum, and from the ileum onwards the circular predominates. In insectivores the longitudinal layer is better developed in the duodenum, but from the jejunum onwards the circular layer is the thicker. In hoofed animals, the circular layer is thicker than the longitudinal, particularly in the duodenum and large intestine.

The intestinal muscles are least developed in rodents and most strongly in carnivores, so it is deduced that motility is more extensive in the first type and more intensive in the second. The powerful development of the muscularis mucosae in the small intestine of carnivores is related not only to the strengthening of movements but also perhaps to an increase in the power of absorption.

H. Scherbatoff.

FOMINA, L. S. Sekretzia kishechnykh fermentov izolerovannymi po Tiri i " denervirovannymi " otrezkami kishok u sobak v zavisimosti ot kolichestva belka v pishche. 1. Kolichestvo kishechnogo sekreta. [**Secretion of intestinal enzymes in intestinal segments isolated by the Thiry method, and in denervated segments, in the dog, in relation to amount of dietary protein. 1. Quantity of intestinal secretion.**] *Vop. Pitan.*, 1955, **14**, No. 3, 16–22. [Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

Four bitches each had a Thiry fistula and a denervated intestinal segment transplanted subcutaneously. One animal was used as a control, the others had a diet deficient in protein. Body-weight, plasma protein concentration and the total amount and percentage of solids in the intestinal secretions from each fistula were studied before and during the period on the deficient diet and at intervals during recovery.

The total amounts secreted by the denervated segments were much less than those from the Thiry loops; in both the amount of juice and percentage of solids fell gradually during protein depletion and rose during recovery.—D. W. Taylor.

537

OTA, S. and SHIBATA, M. **Studies on the mechanism for sugar absorption by rabbit intestine.** *Kyushu Mem. Med. Sci.*, 1954, **5**, 107–121. [Dept. Med. Chem., Fac. Med., Univ. Kyushu.]

A solution of glucose in phosphate buffer containing ^{32}P was injected into the duodenum or bile duct of young rabbits. Portal blood was collected 3 hr. later and a segment of intestine was taken for estimation of P fractions. The results suggested that while phosphorylation was involved in the absorption of glucose from the intestine, dephosphorylation occurred when the glucose was transferred to the portal blood. Little or no ^{32}P was found in the bile from rabbits given the mixture into the bile duct. Monoiodoacetic acid inhibited phosphorylation of glucose during intestinal absorption.

The rate of absorption of different sugars was studied *in vitro* by perfusion through segments of rabbit intestine. The rate of absorption varied

in the descending order galactose, glucose, fructose, ribose, xylose, arabinose. All except arabinose were phosphorylated during absorption, and the phosphorylation system was closely related to the respiratory system and was inhibited by 2 : 4-dinitrophenol, phloridzin or anaerobic conditions. It appeared that phosphorylation took place on the mucous surface of the cells and that residual P was retained in the intestinal mucosa for further phosphorylation. The phosphorylation of fructose differed in some way from that of glucose and was less affected by respiratory inhibitors. Addition of bile promoted exchange of P with glucose, but not with arabinose.—A. M. Copping.

538

FRIDHANDLER, L. and QUASTEL, J. H. **Absorption of sugars from isolated surviving intestine.** *Arch. Biochem. Biophys.*, 1955, **56,** 412–423. [Res. Inst., Montreal Gen. Hosp.]

The absorption of glucose, fructose, sorbose and sucrose from isolated loops of intestine was studied. Glucose appears as well as fructose on the serosal side of the loop when fructose is introduced into the lumen. 2 : 4-Dinitrophenol suppresses glucose formation, but does not reduce the rate of disappearance of fructose. Phloridzin suppresses glucose absorption, but not fructose absorption or the formation of glucose from fructose. The behaviour of fructose, sucrose and sorbose suggests that they are " passively " absorbed.

A. T. Phillipson.

539

FRIDHANDLER, L. and QUASTEL, J. H. **Absorption of amino acids from isolated surviving intestine.** *Arch. Biochem. Biophys.*, 1955, **56,** 424–440. [Res. Inst., Montreal Gen. Hosp.]

L-Isomers of histidine and alanine were absorbed from the isolated intestine more rapidly than the D-isomers. Oxygen lack and dinitrophenol both inhibit the absorption of DL-alanine and phenylalanine, but phloridzin does not. Deoxypyridoxine inhibits absorption of DL-alanine and also of glucose. L-Glutamine passes unchanged through the intestinal mucosa, but asparagine is converted to aspartic acid and ammonia. The expression " active " absorption is used to connote that absorption of the substance in question can be reduced by certain agents or by oxygen lack. [The possibility that inhibitors of intracellular enzymic systems may themselves alter permeability is not discussed.]

A. T. Phillipson.

540

NASSET, E. S., SCHWARTZ, P. and WEISS, H. V. **The digestion of proteins *in vivo*.** *J. Nutrition*, 1955, **56,** 83–94. [Dept. Physiol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Groups of 2, 3 or 4 mongrel dogs were fasted for 24 hr. before being given test meals of 80 per cent. protein, 10 per cent. sucrose and 10 per cent. lard or of 45 or 40 g. lard and 5 or 10 g. sucrose. Water was given to appetite. The animals were killed 1½ hr. after the test meals and the contents of the digestive tract were analysed for total N and N soluble in 70 per cent. ethanol, and 15 " free " amino-acids were estimated microbiologically.

In the small intestine all 15 amino-acids were present in approximately constant proportions after both protein and non-protein test meals, and whether the protein in the test meals was derived from zein or egg albumin. It is concluded that the qualitative amino-acid composition of intestinal contents is not greatly altered by changing from a protein-free to a protein-containing diet.

BUDOLFSEN, S. E. **The absorption of sodium chloride in the colon and the distal part of the small intestine.** *Acta physiol. scand.*, 1954, **32,** 148–162. [Dept. Physiol., Univ. Aarhus.]

The absorption of Na and Cl from segments of ileum and colon was studied in the rat. The amount of each ion absorbed increased with the concentration of the solution introduced over a range of 0·25 to 1·25 per cent. NaCl. Above this value absorption was depressed. Generally more Cl than Na was absorbed. Both ions were absorbed against concentration gradients in both organs.—A. T. Phillipson.

545

WRIGHT, E. **Site of phosphorus absorption in the sheep.** *Nature*, 1955, **176,** 351–352. [Wallaceville Animal Res. Stat., Private Bag, Wellington, N.Z.]

Sheep were allowed to graze until 4 hr. before they were anaesthetised. The part of the intestine under investigation was then tied off and ^{32}P was injected into it. Blood samples were taken at intervals from the left jugular vein.

Absorption from the rumen, omasum, duodenum, colon and caecum was of the same order. From the ileum absorption was 10 times greater, and from the abomasum 100 times greater. It was thought that the mechanism involved was one of simple exchange rather than of true absorption, except in the ileum and abomasum.—T. D. Bell.

COMPOSITION OF BODY FLUIDS AND TISSUES

BLOOD

547

PASSARO, G. and PATANÈ, E. Il volume del sangue nella distrofia da latte vaccino. [**The blood volume in dystrophy due to cow's milk.**] *Arch. ital. Pediat. Puericolt.*, 1955, **17,** 324–334. [Ist. Clin. Pediat., Univ. Rome.] French, English and German summaries.

The subjects were 25 infants aged from 2½ to 20 months, all with typical cow's milk dystrophy. Plasma volume was estimated with polyvinylpyrrolidone as described in Abst. 2104, Vol. 25, and the results were compared with those given in that paper for normal infants.

When expressed as a percentage of bodyweight the plasma volume was within normal limits in 16 infants, but below that of normal infants of the same age in 9. The mean value was 48·4 ml. per kg. Haematocrits were between 22·3 and 33 per cent., and blood volumes between 52·5 and 84·4 ml. per kg. bodyweight; the mean blood volume was 67·7 ml. per kg., against 77·7 for the normal infants. Since the infants were all much below normal weight for age the absolute values for blood and plasma volume were also low.—D. Duncan.

548

MARKS, J., GAIRDNER, D. and ROSCOE, J. D. **Blood formation in infancy. 3. Cord blood.**

GAIRDNER, D., MARKS, J. and ROSCOE, J. D. (with POLLARD, M. J.). **4. The early anaemia of prematurity.** *Arch. Dis. Childhood*, 1955, **30,** 117–120; 203–211. [Maternity Hosp., Cambridge.]

For previous parts see Absts. 2247, Vol. 22 and 500, Vol. 23.

3. Blood from the umbilical vein was collected from 221 infants with birthweights above 2500 g. Hb was estimated as oxyhaemoglobin in a photoelectric colorimeter.

The mean value for Hb was 16·9 g. per 100 ml., 95 per cent. of the values being within the range 13·7 to 20·1 g. Average values are also given for red cell count, haematocrit, mean corpuscular Hb, mean corpuscular volume, reticulocytes and normoblasts. There was no relation between Hb level and foetal maturity. At 7 weeks of age infants born with low Hb showed values similar to those of infants born with high Hb.

4. Samples of venous blood for Hb and haematocrit estimations were taken at intervals from 31 premature infants of birthweight less than 1620 g. Blood volumes were computed from bodyweights and haematocrit values and the rate of decline of total Hb during the first few weeks of life was estimated.

Marrow samples were examined on 29 occasions at ages ranging from 26 to 99 days. These revealed no difference between premature and full-term infants.

The data presented suggest that the slow response of erythropoiesis to the stimulus of anaemia in infants is exaggerated by more rapid growth in the premature infant. Rapid growth also prolongs the anaemia once this has developed. Iron was given to 13 infants from about the second week and in a control group also of 13 infants it was withheld until Hb had fallen to 11 g., usually at about the sixth week. The remaining 5 infants were given Co and Fe from about the second week. In the group given Fe early the average Hb level between 60 and 100 days was significantly higher than in the controls. This treatment is recommended to mitigate the early anaemia of prematurity. Addition of Co caused a striking increase in erythropoiesis, usually sufficient to prevent development of anaemia, but because of

its toxic effect on the thyroid this treatment is not recommended.—F. C. Aitken.

549

SEIP, M. **The reticulocyte level, and the erythrocyte production judged from reticulocyte studies, in newborn infants during the first week of life.** *Acta paediat.*, 1955, **44,** 355–369. [Child. Hosp., Univ. Oslo.] French, German and Spanish summaries.

In healthy full-term infants the average reticulocyte count on the first day of life was 51·9 per thousand red cells, range 41·6 to 63·0, compared with 15·7, range 9·6 to 23·8, in normal adults. Values were higher in premature and lower in postmature infants. The reticulocyte count remained almost constant for 3 days after birth and in the next 2 to 3 days dropped rapidly to normal adult values. The formation of red cells and Hb at birth was 3 to 5 times as rapid as in healthy adults, depending on the basis of comparison. During the first 3 days after birth red cell production continued to be very rapid and then fell to normal adult values within 2 or 3 days. A study of newborn infants with prolonged asphyxia indicated that changes in reticulocyte count and rate of red cell formation in the first week of life are related to changes in oxygen supply after birth. Reasons for the 3-day lag before the changes occur are discussed.—F. C. Aitken.

550

LEICHSENRING, J. M., NORRIS, L. M., LAMISON, S. A. and HALBERT, M. L. **Blood cell values for healthy adolescents.** *Amer. J. Dis. Child.*, 1955, **90,** 159–163. [Sch. Home Econ., Univ. Minnesota, St. Paul.]

The subjects were rural young people, 110 boys and 130 girls aged from 12 to 21 years, who had been medically selected in 1947 or 1949 as 4-H Club health champions of their counties in Minnesota State. Hb was estimated in finger blood by the alkaline haematin method and red cell count by a photoelectric method. Red cell diameters and reticulocyte counts were ascertained. Means and standard deviations and ranges are tabulated for each year from 12 to 17 and for those of 18 and over.

For boys, mean Hb value rose from 13·0 $\pm$ 0·71 g. per 100 ml. at 12 to 15·1 $\pm$ 0·76 at 16, and red cell count from 4·24 $\pm$ 0·21 millions per c. mm. to 4·85 $\pm$ 0·36; these values are below those of Wiehl (Abst. 3148, Vol. 11) for boys from well-to-do families in New York City. For girls, mean Hb value was 13·0 $\pm$ 0·61 at 12, but fell to 12·7 $\pm$ 0·81 at 16 and rose again to 13·3 $\pm$ 0·48 at 18 and over; these values are above those found in an earlier study of Minnesota high school girls (Leichensring *et al.*, *Amer. J. Dis. Child.*, 1941, **62,** 262). Mean red cell count was 4·31 $\pm$ 0·17 at 12 and 4·19 $\pm$ 0·27 at 16, rising again to 4·34 $\pm$ 0·20 at 18 and over. Mean corpuscular Hb did not vary with age in either sex, nor did red cell diameter or reticulocyte percentage.—W. M. Deans.

551

WALKER, A. R. P. **Haemoglobin concentration and nutritional state in South African Bantu habituated to a very high iron intake.** *S. African J. Lab. Clin. Med.*, 1955, **1,** 36–44. [Human Biochem. Unit, S. African Inst. Med. Res., Johannesburg.]

Hb was estimated in the blood of 3 groups of men passed as medically fit for work in the mines and groups of male and female farm labourers, male and female malnourished hospital patients, pregnant and non-pregnant peri-urban women and healthy female nurses. Group mean Hb values were within or very little below normal limits. The occurrence of approximately normal Hb levels despite the strain of heavy intestinal parasitic infestation in some of the groups, of severe malnutrition in others and of pregnancy in one of the groups of women, is attributed to the Bantu's high intake of Fe, mostly from cooking utensils.

F. C. Aitken.

552

GOETZ, R. H. and BUDTZ-OLSEN, O. **Scientific safari—the circulation of the giraffe.** *S. African Med. J.*, 1955, **29,** 773–776. [Dept. Surg. Res., Univ. Cape Town.]

Data are given for the blood of a giraffe: red cells 11·95 million per c.mm., haematocrit 47 per cent. and Hb 17·8 g. per 100 ml. Viscosity of serum and its protein content, 4·3 g. per 100 ml., were comparable with findings for man. By a catheter 8 ft. long inserted to reach the bifurcation of the carotid artery, blood pressure was found to be 200 mm. Hg in the upright position and to fall to 175 mm. Hg when the head was lowered. No trace of arteriosclerosis was found in an aged bull giraffe.—D. Harvey.

553

ROSSI-FANELLI, A., CAVALLINI, D. and DE MARCO, C. **Amino-acid composition of human crystallized myoglobin and haemoglobin.** *Biochim. biophys. Acta*, 1955, **17,** 377–381. [Inst. Biochem., Univ. Rome.] French and German summaries.

Human myoglobin and Hb were quantitatively analysed for amino-acids by ion-exchange chromatography. Myoglobin contained more glutamic acid, lysine, glycine and methionine and less threonine, alanine, valine and arginine than Hb. *Iso*-leucine was absent from Hb and cystine from myoglobin. Hb had 621 amino-acid residues, myoglobin 151.—A. Hepburn.

DERRIEN, Y. and LAURENT, G. Différenciation par leur teneur en isoleucine des hemoglobines alcalinorésistantes de l'homme adulte et du nouveau-né. [**Differentiation by their content of *iso*leucine of alkali-resistant haemoglobins of adult man and newborn infant.**] *C.R. Acad. Sci.*, 1955, **241,** 450–452.

The alkali-resistant fractions of oxy- and carboxyhaemoglobin in normal adult blood and carboxyhaemoglobin in blood from the umbilical cord of newborn infants contained 3·25, 1·9 and 1·94 g. *iso*leucine per 100 g. Hb, respectively. Total adult carboxyhaemoglobin contained 0·34 g. *iso*leucine. The values suggested the existence of 2 types of alkali-resistant Hb in adult carboxyhaemoglobin.—A. Hepburn.

HOLMES, E. G., STANIER, M. W. and THOMPSON, M. D. **The serum protein pattern of Africans in Uganda: relation to diet and malaria.** *Trans. Roy. Soc. Trop. Med. Hyg.*, 1955, **49,** 376–384.

The subjects, who were free from serious illness, were living in 3 contrasting areas: (1) around Kampala where malaria is hypo-endemic and diet almost completely vegetarian, (2) in Karamoja where malaria is seasonal and habits are pastoral with good supplies of milk and meat and (3) in Kigezi, where malaria is relatively rare and diet is again largely vegetarian but may have more protein than that in the Kampala area. Serum protein were estimated in 36, 40 and 21 adults in these areas and in 10 Europeans and 8 African students as control subjects. The mean values for all Africans differed from those for Europeans; in comparison with the first group, the second had higher total protein, albumin and γ-globulin and the third higher albumin and lower γ-globulin levels. Children also were examined in the districts; their numbers and average age in months were, Kampala 8, 44: Karamoja, 2, 52: Kigezi, 10, 29. In Karamoja the means for albumin and γ-globulin were both greater than those in Kampala and Kigezi. Haematological data are given for 343 Africans in Kampala, for 122 in Karamoja and for 49 African students as controls. The mean red cell count for the second was higher than that for the first and comparable with that for the controls, but the Hb level was the lowest of the 3 groups.

From the difference in findings for children and adults it is concluded that, while accurate dietary survey data are not available, no relation exists between levels of protein in diet and of albumin or γ-globulin in blood. It is suggested that the deviation of the pattern of blood proteins for Africans from that for Europeans may be the result of the seasonal infection with malaria which the populations experience.

Clinical data for the Karamoja and Kigezi populations are included in a small appendix.

YÜ-CHENG, M. **Levels of plasma protein fractions in normal Chinese adults.** *Chinese Med. J.*, 1954, **72,** 438–445. [Clin. Chem. Lab., Chinese Union Med. Coll., Peking.]

Three groups of healthy subjects aged from 18 to 55 years, 90 per cent. of them men, were studied from 1935 to 1937. In 36 well fed subjects the mean serum values in g. per 100 ml. were for total protein 6·490 $\pm$ 0·032 and for albumin 4·084 $\pm$ 0·055; the albumin : globulin ratio was 1·90 $\pm$ 0·05. In 108 less well but adequately fed subjects the corresponding figures were 6·714 $\pm$ 0·046, 4·063 $\pm$ 0·029 and 1·74 $\pm$ 0·03, and in 25 subjects on a mainly vegetarian diet the values were 6·287 $\pm$ 0·14, 3·618 $\pm$ 0·082 and 1·55 $\pm$ 0·05. The

albumin value fell with the amount of meat in the diet.—L. Wills.

GOTTFRIED, S. P., POPE, R. H., FRIEDMAN, N. H., AKERSON, I. B. and DI MAURO, S. **Serum beta-lipoproteins of normal, atherosclerotic, and lipemic individuals: changes in concentration, stability, and mobility upon incubation at 6·5° and 37·5°, as determined by paper electrophoresis.** *Clin. Chem.*, 1955, **1,** 253–263. [Dept. Biochem., Bridgeport Hosp., Bridgeport, Conn.]

The concentrations of β-lipoproteins in serum from 8 normal, 7 atherosclerotic and 8 lipaemic fasting human subjects fell equally when the serum was incubated at 6·5° or 37° C. for 24, 48 and 72 hr. The mobility of β-lipoproteins increased at 37° C., except when turbidity appeared, when mobility fell; turbidity appeared mostly after 48 hr. and was more common in atherosclerotic than in normal sera. As turbidity advanced a protein fraction, probably denatured protein, appeared, formed apparently at the expense of the β- and γ-globulins and later of the α-globulins, all of which decreased. Incubation at 6·5° C. had no effect on turbidity or mobility. No consistent change was found in concentration, stability or mobility of α-lipoproteins upon incubation.—A. Hepburn.

571

GAMBASSI, G. and MAGGI, V. Il quadro proteico nell'aterosclerosi sperimentale colesterolica: contributo all'interpretazione dell'effetto anti-ateromasico dell' ATP. [**The protein picture in experimental cholesterol atherosclerosis: a contribution to the interpretation of the effect of ATP against atheroma.**] *Acta gerontol.*, 1955, **5,** 260–216. [Ist. Clin. Med., Univ. Ferrara.] French and English summaries.

The rabbits received cholesterol, 0·5 g. daily for 140 days, and 3 groups received adenosine

triphosphate (ATP) as described in Abst. 562, Vol. 25. The serum proteins and lipoproteins were studied.

There was a significant difference in the electrophoretic distribution of albumin and α- and β-globulins between the controls and the group most effectively protected against atherosclerosis by ATP given subcutaneously. In the latter group the albumin fraction was greater and the globulins less. In this group also the serum and liver phosphatide contents were highest and those of neutral fats lowest. There was no significantly constant ratio between the protein and lipid fractions commonly thought to be atherogenic.

It is concluded that the protein fractions separated by electrophoresis do not correspond to the lipoprotein fractions of serum.—D. Duncan.

572

PASSARO, G. I mucoproteidi serica secondo Winzler nella patologia pediatrica. [**The serum mucoproteins according to Winzler in paediatric pathology.**] *Arch. ital. Pediat. Puericolt.*, 1955, **17,** 335–361. [Ist. Clin. Pediat., Univ. Rome.] French, English and German summaries.

Mucoproteins were estimated by the method of Winzler *et al.* (Title 3924, Vol. 18) in blood serum from 155 infants in the first year of life, before and usually during treatment of different disorders.

Increases in serum mucoproteins were found in rheumatic disease, bronchopneumonia, pneumonic miliary tuberculosis, tuberculous or purulent meningitis, encephalitis, Hodgkin's disease, acute lymphatic leucaemia, osteomyelitis, appendicitis, and glomerulonephritis with azotaemia. Values were reduced in lipoid nephrosis and in hypothyroidism, but normal in rheumatoid arthritis, congenital heart diseases, bronchiectasis, haemolytic anaemias, cow's milk dystrophy and other disorders.

It is concluded that increases in serum mucoproteins accompany inflammatory or proliferative processes, and that they are proportional to the severity of these.—D. Duncan.

573

JONES, R. J., COHEN, L. and CORBUS, H. **The serum lipid pattern in hyperthyroidism, hypothyroidism and coronary atherosclerosis.** *Amer. J. Med.*, 1955, **19,** 71–77. [Dept. Med., Univ. Chicago, Ill.]

Blood from 17 hypothyroid and 25 hyperthyroid patients was examined. In the first, mean values for total lipids, total cholesterol and phospholipins and for β-lipoprotein and the faster rising components were significantly higher than in the second group; the values for α-lipoprotein did not differ significantly. When patients with coronary heart disease were matched with hypothyroid patients for sex, age and cholesterol level in serum, the β-lipoprotein fraction was found to be significantly greater in the first of these groups. The mechanism of the changes which result in high levels of fat in blood is concluded not to be the same in these 2 diseases.—D. Harvey.

574

TELLERIA DIAZ, J. E. Influencia del lipocaico sobre la colesterolemia. [**Influence of lipocaic on blood cholesterol.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4,** 299–311.

Three groups of rabbits were fed on greenstuff, maize and water. Blood serum cholesterol was estimated before and 1, 2, 4, 8, 12, 16 and 24 hr. after intramuscular injection of lipocaic; 10 rabbits received 100 mg., 10 had 200 mg. and 5 had 400 mg. per kg. bodyweight.

The initial values for cholesterol lay between 16·5 and 52·8 mg. per 100 ml. serum, mean 34·65. In all the rabbits lipocaic caused a drop in serum cholesterol which was usually greatest 4 hr. after the injection and was usually followed by a rise to above the initial value. The mean fall, as a percentage of the initial value, was after 100 mg. lipocaic 24·2, after 200 mg. 35·3 and after 400 mg. 45·7. The initial value was regained within 16 hr. after the smallest dose and in 24 hr. after the others.

D. Duncan.

POOLE, J. C. F. **The effect of certain fatty acids on the coagulation of plasma *in vitro*.** *Brit. J. Exp. Pathol.*, 1955, **36,** 248–253. [Sir William Dunn Sch. Pathol., Univ. Oxford.]

The coagulation of recalcified citrated human plasma was accelerated by low concentrations of the Na salts of stearic, palmitic and oleic acids; the salts of acetic, butyric, valeric, caproic, caprylic, pelargonic, lauric, myristic, elaidic, linoleic and ricinoleic acids were without effect. It is concluded that, if such an effect occurs *in vivo*, the increase in concentration of free fatty acids in blood in rats after a fat meal (Abst. 3837, Vol. 25) would be more than sufficient to account for the increased coagulability of blood on such diets.

ÖSTERLUND, K. **A comparative investigation of the concentration of certain electrolytes in maternal and cord blood.** *Ann. Paediat. Fenn.*, 1954–55, **1**, Suppl. No. 4, pp. 87. [Child. Clin., Univ. Helsinki.]

Samples of maternal arterial and venous blood obtained before or after parturition and samples from the cord vessels of 120 infants were analysed.

Alkali reserve in maternal blood was significantly higher in venous than in arterial samples and that in cord blood was significantly higher in arterial than in venous samples. Maternal alkali reserve was highly significantly lower than that of the infant.

Plasma chloride level was lower in maternal venous than in arterial blood. Cell chlorides were significantly higher in maternal venous than in arterial blood. In cord blood plasma chloride level was lower in arterial than in venous blood and cell chlorides were significantly higher in arterial than in venous blood. Maternal values were lower than infant values, the difference being highly significant in cell chlorides.

A similar study of plasma and cell K revealed only one significant difference, the higher level of K in the plasma of cord compared with maternal blood. For Na the only significant difference was in the higher cell Na in infant than in maternal blood.

The results indicate that the newborn infant or the foetus is acidotic and that the acidosis is metabolic.—F. C. Aitken.

JANKE, B. and SCHARPFF, D. Klinische Untersuchungen über den Natrium-, Kalium- und Kalzium - Stoffwechsel. [**Clinical studies of sodium, potassium and calcium metabolism.**] *Deutsch. med. Wochenschr.*, 1953, **78**, 816–819 (conclusion). [Inn. Abt., Kreiskrankenhaus, Heidenheim.]

For earlier part see Title 4685, Vol. 23.

Normal values for blood Na, K and Ca in 100 carefully examined subjects were, in mg. per cent.: Na in 13, 260 to 295, in 59, 295 to 310, in 24, 310 to 330 and in 4, 330 to 350, mean 305; K in 25, 15·0 to 17·0, in 46, 17·0 to 18·0, in 29, 18·0 to 20·3, mean 17·6; Ca in 31, 7·0 to 8·5, in 49, 8·5 to 9·5, in 20, 9·5 to 11·5, mean 9·4. These values were got in the winter, between November and February. Further analyses showed that Na fell between February and June; both K and Ca rose without change in the ratio K : Ca, which was 1·8 throughout. Values are given also for K in patients with cardiac disease, liver disease, diabetes and hyperthyroidism and are discussed in relation to changes in the electrocardiogram.—I. Leitch.

CUADROS CH., C. Influencia del BAL sobre calcio y potasio sanguíneos. [**Influence of BAL on blood calcium and potassium.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 196–214.

The experiments were made on 4 groups of 8 rabbits weighing between 1600 and 2700 g., which received intramuscularly or intraperitoneally 2·5, 10, 20 or 40 mg. BAL per kg. bodyweight. The rabbits were fasted and blood samples were taken before and 2, 4, 6, 8, 10 and 12 hr. after the injection for estimation of serum Ca and K.

The basal values for Ca were from 13·34 to 16·56 mg. per 100 ml. serum, mean 15·29, and BAL produced maximum falls of from 8·17 to 8·64 per cent., without relation to the dose of BAL. The basal values for K were from 18·23 to 24·62 mg. per 100 ml., mean 20·94. BAL produced increases in serum K which varied with the dose from 6·27 per cent. after 2·5 mg. per kg. to 15·17 per cent. after 40 mg. per kg. The K : Ca ratio therefore rose with the dose of BAL.—D. Duncan.

583

SILVERMAN, S. H. and GARDNER, L. I. **Ultrafiltration studies on serum magnesium.** *New Engl. J. Med.*, 1954, **250**, 938–941. [Dept. Paediat., Sch. Med., Johns Hopkins Univ., Baltimore, Md.]

The mean values of serum total and ultrafiltrable Mg in 43 normal infants and children 3 months to 12 years old were 1·77 and 1·16 m. equiv. per litre. The range was narrow; the

values did not vary with age and were similar to adult values. The percentage of ultrafiltrable Mg was 65·3. Normal values were found in 7 children with nephrosis and in children with epilepsy, Legg-Perthes disease and infectious hepatitis. No increase in ultrafiltrable Mg was found in 5 congenital cretins and 2 children with juvenile hypothyroidism. Total serum Mg was high in 3 adults with chronic nephritis. It was high also in 2 children with chronic hypothermia and rheumatic heart disease immediately after death. It was low in 2 patients treated with massive doses of vitamin D.—A. Hepburn.

584

CARRANZA, C., C. R. Cupremia en estados normal y patológico. [**Blood copper in normal and pathological conditions.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 183–195.

Cu was estimated in plasma from 30 apparently healthy students in Lima and 60 anaemic patients with other disorders. The ranges and mean values and standard deviations, in μg. per cent., were for 15 healthy women aged 22 to 27 years 92 to 143, 114·6 and 12·18; for 15 healthy men aged 22 to 30 years 88 to 122, 105·3 and 8·06; for 10 tuberculous patients aged 16 to 62 years 194 to 320, 269 and 42·1; for 9 patients with glomerulonephritis 209 to 324, 262·1 and 31·5; and for 7 patients with arteriosclerosis 250 to 321, 281 and 28·4. The values were high in all the other patients, who had diverse diseases. There was a general inverse correlation between plasma Cu and haematocrit.—D. Duncan.

585

HAMMERSCHMIDT R., V. Cupremia en enfermedades del sistema nervioso. [**Blood copper in disorders of the nervous system.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 224–233.

Plasma Cu was estimated in 25 male and 20 female patients aged from 22 to 89 years, of whom 6 had a diagnosis of chorea, 6 athetosis, 15 post-encephalitic Parkinsonism and 18 Parkinson's syndrome. For these 4 groups the ranges, mean values and standard deviations, in μg. per 100 ml. plasma, were 172 to 205, 189 and 11·76; 123 to 257, 202 and 39·6; 164 to 257, 208 and 27·2; and 148 to 274, 214 and 30. It is concluded that plasma Cu is high in nervous disorders involving extrapyramidal lesions.—D. Duncan.

LETTERER, E., GEROK, W. and SCHNEIDER, G. Vergleichende Untersuchungen über den Amino-säurenbestand von Serum-Eiweiss, Lebereiweiss, Amyloid, Hyalin and Kollagen. [**Comparative studies of the amino-acid composition of serum protein, liver protein, amyloid, hyalin and collagen.**] *Virchows Arch.*, 1955, **327**, 327–342. [Pathol. Inst., Univ. Tübingen.]

Amyloid and hyalin from affected human organs *post mortem* and soluble liver protein from livers of freshly killed mice were subjected to paper chromatography. Soluble liver protein resembled serum α- and β-globulin and had the following composition (mean of 8 preparations); glycine, alanine, valine and the leucines 35·1, serine and threonine 11·3, cysteine and methionine 3·3, aspartic and glutamic acids 26·8, lysine and arginine 11·1, phenylalanine and tyrosine 6·1, proline 4·1 per cent., hydroxyproline traces only. Amyloid and hyalin had a composition intermediate between that of soluble liver protein and collagen, and are probably mixtures of proteins.—W. M. Deans.

NOBLE, N. L. and BOUCEK, R. J. **Lipids of the serum and connective tissue of the rat and rabbit.** *Circulation Res.*, 1955, **3**, 344–350. [Res. Lab., Miami Heart Inst., Sch. Med., Univ. Miami, Coral Gables, Fla.]

Rabbits and rats were maintained on stock diets and connective tissue specimens were removed at different times from 14 to 140 days after implantation of sponge. Lipids were isolated from the connective tissue and analysed for total and ester cholesterol, total fatty acids, and total and choline-containing phospholipins.

The concentration of total lipids in both rat and rabbit connective tissue was very high compared with the lipid content of other tissues; the total cholesterol concentration was especially high, the mean values being 3·08 g. and 1·77 g. per 100 g. dry weight, respectively, for rats and rabbits. The concentrations of neutral fat and cholesterol increased significantly with the age of the tissue. No significant correlation was found between lipid values in serum and connective tissue in either species.—G. A. Garton.

FRAILE OVEJERO, A. and LLUCH TRULL, M. Variaciones del peso de los órganos del ratón en ayunas; influencia de las cápsulas adrenales. [**Variations in weight of organs of the fasting mouse; influence of the adrenals.**] *Rev. española Fisiol.*, 1955, **11**, 57–62. [Lab. Fisiol. Animal, Fac. Farm., Univ. Barcelona.] English summary.

The mice, of both sexes, were from 100 to 500 days old and weighed initially from 12 to 31 g. They were fasted, with water only, until they died. The adrenals were removed after 24 hours' fasting from 18 males and 9 females. When the mice died, organs were weighed fresh and after drying.

The percentage of the initial weight lost before death, in males and females, was 25·7 and 31·7 in normal mice and 15·0 and 15·1 in those with

adrenals removed. Whereas in normal mice the percentage loss of liver and spleen was twice that of the whole body, in mice with adrenals removed the spleen lost no weight or even gained, though the liver lost. The heart and kidneys lost hardly any weight after adrenalectomy. [There is no mention of how long the mice survived.]

The results are compared with those obtained with rats (Abst. 670, Vol. 25).—D. Duncan.

598

WANG, C. I., SCHAEFER, L. E. and ADLERSBERG, D. **Experimental studies on the relations between adrenal cortex, plasma lipids, and atherosclerosis.** *Endocrinology*, 1955, **56,** 628–638. [Dept. Med., Mount Sinai Hosp., New York.]

In rabbits treated with cortisone or hydrocortisone the plasma became opaque and the plasma lipid fractions, especially neutral fat and total lipids, increased. The effects resembled those of dietary cholesterol and were additive with the latter, but when the hormones were given with a high-cholesterol diet there was less atherosclerosis than with the diet alone.

Changes in the dog were similar, but of smaller magnitude than in the rabbit.—D. Duncan.

[**The parathyroid glands and their relations with endocrine glands and organ systems in connection with mineral metabolism.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 73–94; 125. [Pathol. Inst., Univ. Göttingen.]

The author's own work and that of others is reviewed, with 117 references.

It is concluded that there is no parathyrotropic hormone and that the parathyroid is independent of other endocrine glands. The only organ with which it has a close metabolic link is the kidney. In kidney disorders the parathyroid becomes hyperactive; the mechanism by which the parathyroid is stimulated is still the subject of controversy. Conversely, parathyroid hormone affects the kidney, especially the excretion of phosphate. The parathyroid also affects the skeleton, but again the mechanism of the relation is not clear. In rats poisoned with uranium nitrate the kidneys were damaged, the parathyroids became enlarged and osteodystrophy developed, which could be prevented by treatment with vitamin D. Experimental rickets in rats was influenced by the parathyroid. Massive doses of Vigantol reduced the activity of the parathyroid. Vitamin A stimulated it. There is no sure evidence that the parathyroid produces more than one hormone.

KLINCK, G. H. **Thyroid hyperplasia in young children.** *J. Amer. Med. Assoc.*, 1955, **158,** 1347–1348. [Armed Forces Inst. Pathol., Washington, D.C.]

In this study of 10 young children and infants with thyroid enlargement, cobaltous chloride and ferrous sulphate had been given to 5 of the patients. Histological study of the enlarged thyroids failed to differentiate between those from the children who had and those who had not received Co and Fe. The goitrogenic activity of Co was not established, but as the number was small, further study of a larger series is recommended.—B. W. Simpson.

605

JAIMET, C. H. and THODE, H. G. **Thyroid function studies on children receiving cobalt therapy.** *J. Amer. Med. Assoc.*, 1955, **158,** 1353–1355. [Hamilton Coll., McMaster Univ., Hamilton, Ont.]

Clinical examinations and studies of thyroid function were made on 17 children aged 5 to 9

years. Uptake of ^{131}I, conversion ratio and saliva protein-bound iodine activity were measured 24 hr. after a tracer dose of 50 μC. ^{131}I had been given to all the children. On the next day, medication with a liquid cobalt-iron preparation was begun; 4 children received 1 mg. cobaltous chloride per kg. bodyweight, 5 received 2 mg., 4 received 4 mg. and 5 received 6 mg. per kg. bodyweight daily. Five and 10 weeks after treatment was begun, thyroid function was again tested.

None of the children developed hypothyroidism. It is suggested that the difference of opinion that has arisen about the effect on the thyroid gland of administration of Co may be due to the presence of toxic impurities in some commercial samples of cobaltous chloride. It is also considered possible that some diseases may alter the thyroid cells so as to render them permeable to Co.—B. W. Simpson.

606

HOLLY, R. G. **Studies on iron and cobalt metabolism.** *J. Amer. Med. Assoc.*, 1955, **158,** 1349–1352. [Dept. Obstet. Gynaecol., Univ. Nebraska Coll. Med., Omaha.]

From 60 to 90 mg. cobaltous chloride daily and an iron salt were given to 58 pregnant women. Another 20 pregnant women were given daily 75 to 100 mg. $CoCl_2$ without Fe and 94 received Fe alone. All supplements were given for at least 90 days before delivery; 55 normal pregnant women served as controls. There was no toxic effect of the Co and the thyroids were not enlarged. Examination failed to disclose thyroid enlargement in any of the children born to the mothers given Co.

In experiments on mice and rats $CoCl_2$ was injected intraperitoneally with and without $FeSO_4$. Erythropoiesis was stimulated but no thyroid enlargement or other abnormality was observed. Renal tubular necrosis was seen only in some animals given large doses of Co.—B. W. Simpson.

607

SCOTT, K. G. and REILLY, W. A. **Cobaltous chloride and iodine metabolism of normal and tumor-bearing rats.** *J. Amer. Med. Assoc.*, 1955, **158,** 1355–1357. [Dept. Radiol., Univ. California Sch. Med., San Francisco.]

Rats were divided into 5 groups of 5 each; 1 group was untreated, 2 groups were given cobaltous chloride and 2 were given cobaltous chloride and ferrous sulphate in their drinking water for 44 days. Some of the rats in the control group and 1 of each of the other groups were given a tumour implant 13 days before the experiment ended. A tracer dose of ^{131}I was given to all the rats 66 hr. before they were killed.

Haematopoiesis was stimulated and tumour growth was inhibited in the experimental groups, but there was no inhibition of uptake of ^{131}I by the thyroid, and synthesis and release of thyroxine were not affected by the Co. The daily intake was about 60 mg. per kg. bodyweight and this amount of Co had no appreciable effect on I metabolism within the 44 days.—B. W. Simpson.

608

HARE, E. H. and HAIGH, C. P. **Variations in the iodine avidity of the normal human thyroid as measured by the 24-hour ^{131}I uptake.** *Clin. Sci.*, 1955, **14,** 441–449. [Barrow Hosp., Bristol.]

The percentage uptake of ^{131}I by the thyroids of 28 euthyroid subjects in 24 hr. after a dose of 7 μC. of carrier-free ^{131}I was measured with a Geiger counter. The investigations were repeated on several occasions on each subject. The variations of uptake were considerable and the degree of variability was greater than the probable range of experimental error. Variability was not related to age, sex, menstruation, route of administration or the presence of chronic psychosis. A rising mean day temperature during the week before the test was often associated with lower uptake and vice versa. It is suggested that ^{132}I, with its shorter half-life of 2·3 hr., might be of more value than ^{131}I in an investigation such as this, because of the danger of ^{131}I being left from one test to another.

609

VAN MIDDLESWORTH, L. **Goiter production and prevention in rats.** *Science*, 1955, **121,** 871–873. [Dept. Physiol., Univ. Tennessee, Memphis.]

A commercial cereal, Cereal-G, contained from 0·015 to 0·035 μg. iodine per g. Its goitrogenic effect on rats was compared with that of the Remington diet (Abst. 645, Vol. 7), which contained 0·08 μg. I per g., and of diets containing Cereal-G with 13 per cent. sucrose and Cereal-G with 26 per cent. casein, which contained 0·03 and 0·05 μg. I per g., respectively. Groups of rats of 60 to 100 g. bodyweight were fed on these diets for from 6 weeks to 2 years. At different times rats on each diet were killed and their thyroids were compared.

Cereal-G produced goitres sooner than the Remington diet, but after 18 to 26 months the thyroids of rats on the Remington diet were as large as those of the rats given Cereal-G for 12 months. The Remington-fed rats were much heavier. The growth of the rats on Cereal-G was retarded. A diet containing sucrose and casein was much less goitrogenic than Cereal-G and casein, although both had the same I content. Addition of casein to Cereal-G reduced goitre formation and stimulated growth. The withdrawal of casein from this diet produced the largest goitres; one gland weighed 492 mg. But there was great variation in this group and when the data were

examined statistically there was no significant difference between the mean thyroid weight and that of the group given the Remington diet or Cereal-G for the longest period.

The addition of 1·5 μg. NaI daily to the Cereal-G diet almost prevented goitre and 3 μg. NaI daily resulted in thyroids of the same size as the controls.

Interpretations of the results are discussed.

B. W. Simpson.

ABELIN, I. Einfluss der Ernährungsart auf den Verlauf der experimentellen Hyperthyreose. [**Influence of diet on the course of experimental hyperthyroidism.**] *Klin. Wochenschr.*, 1955, **33**, 205–211. [Med. Chem. Inst., Univ. Berne.]

The importance of the protein, fat, carbohydrate, vitamin and mineral constituents of the diet in hyperthyroidism is discussed with reference also to energy intake. The content of cholesterol in the adrenal and of glycogen in the liver and muscle, and the basal metabolic rate, were measured in groups of rats having diets of natural foodstuffs and treated with thyroid preparations. Damage due to hyperthyroidism was ameliorated when the fat content of the diet was above 10 per cent. and when protein from milk, egg, fish, liver, kidney or lean meat was included. An adequate supply of all vitamins was essential and also a supply of minerals, especially Fe, Cu and Mn. From the results of these observations on rats some recommendations are made about diets suitable for patients with hyperthyroid conditions.

MIGHORST, J. C. A. Het verband tussen de activiteit van de schildklier en de eiwitstofwisseling. [**Relation between thyroid gland activity and protein metabolism.**] *Versl. Landbouwk. Onderzoek.*, 1953, No. 59.1, pp. 86. English summary.

The discovery of antithyroid substances and the use of radio-active iodine have produced a great deal of work in the last 10 years, most of it on conventional lines and with little or no bearing on the question of how the thyroid accelerates metabolism. The deduction of Niemann and Redemann (*J. Amer. Chem. Soc.*, 1941, **63**, 1549) that thyroxine acts as a reducing agent has been neither confirmed nor denied. The tests described here showed that methylthiouracil, 50 mg. daily for 10 days, caused hypothyroidism in young cocks only if the protein content of the diet was adequate, N content over 1·9 per cent. The mean $d : n$ value (Lever, *Thesis*, Utrecht, 1950), *i.e.*, the ratio of the internal diameter (d) to the number (n) of cells in the wall of a follicle cut through the middle, is a measure of the metabolic rate; there is no relation to the amount of colloid in follicles. When casein is added to a low-protein diet to raise the protein content to 10 per cent., thyroid activity increases if thiouracil is given. Protein itself increases thyroid activity. Thiouracil reduces growth only if protein intake is adequate; on a low-protein diet birds given thiouracil may grow faster than those without.

Studies with thiouracil and thyroxine on growing mice also are reported.—I. Leitch.

ADEZATI, L., MISSALE, G. and TOSCA, L. Studi sul gozzo endemico. [**Studies on endemic goitre.**] 1. I coenzimi piridinici tiroidei. 1. [**Pyridine coenzymes of the thyroid gland.**] ADEZATI, L. and MISSALE, G. 2. L'attività proteolitica tiroidea. [**2. Proteolytic activity of the thyroid gland.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 991–992; 993–994. [Ist. Clin. Med., Univ. Genoa.]

1. Rats were kept for about 2 months in a region of endemic goitre, in close proximity to the houses of families with a high incidence of goitre. Others were maintained on the same diet in the home laboratory. In the normal and goitrous groups, respectively, the mean weight of the thyroid glands, in mg. per cent. of bodyweight, was 31·6 and 44·6. Pyridine coenzymes were estimated by the method of Robinson *et al.* (Abst. 4462, Vol. 17) in the thyroid glands, and expressed as mg. diphosphopyridine nucleotide per 100 g. fresh tissue. The mean value was for the normal rats 20·3 with range 18·3 to 24·1, and for the goitrous 14·3 with range 12·8 to 16·4.

2. Rats were made goitrous as just described by a sojourn in the commune of Bargagli, Appennino Ligure, and the proteolytic activity of the thyroid glands and of glands from normal rats was estimated from the amount of tyrosine liberated by homogenates of the gland in acetate buffer with edestin as substrate. The mean weight of the glands, in mg. per cent. of bodyweight, was 27·8 for normal rats and 40·7 for the goitrous rats. The mean amount of tyrosine liberated per 100 g. fresh tissue per hr. was for normal rats 181, with range 178 to 185, and for goitrous rats 152, with range 138 to 174.—E. M. Hume.

613

ROBBINS, J. and RALL, J. E. **Thyroxine-binding capacity of serum in normal man.** *J. Clin. Invest.*, 1955, **34**, 1324–1330. [Sloan Kettering Inst. Cancer Res., New York.]

Serum samples were taken after an overnight fast from 6 normal young adults, 1 patient with Graves' disease and 1 cretin who was being maintained on triiodothyronine. Dried synthetic thyroxine labelled with ^{131}I was added so as to produce a wide range of thyroxine concentrations in the

serum from each subject. The thyroxine-binding capacity of the serum protein was estimated. Each serum and thyroxine mixture was studied by zone electrophoresis in filter paper at *p*H 8·6 and the distribution of ^{131}I among the serum protein components was studied.

At the lower thyroxine concentrations the thyroxine-^{131}I was found to be associated with globulins. As the thyroxine content increased, thyroxine-^{131}I became more associated with albumin and less with α-globulin. All the added thyroxine was bound to protein, but the specific thyroxine-binding protein (TBP) had a limited capacity and excess thyroxine was bound to other serum proteins, notably albumin. TBP itself could not be isolated from the other α-globulins. The saturation of TBP by thyroxine occurred at serum thyroxine levels at least 2 or 3 times normal. In the serum from the cretin the concentration of thyroxine on α-globulin continued to increase throughout the range employed. None was found on albumin. In the hyperthyroid patient it was uncertain whether the values obtained differed from normal. Endogenous and added thyroxine seemed to be interchangeable.—B. W. Simpson.

614

ROBBINS, J. and RALL, J. E. **Effects of triiodothyronine and other thyroxine analogues on thyroxine-binding in human serum.** *J. Clin. Invest.*, 1955, **34,** 1331–1336. [Sloan Kettering Inst. Cancer Res., New York.]

Sera from 3 healthy young adults were obtained after overnight fasts and added to 14 analogues of thyroxine and L-thyroxine-^{131}I combined in different concentrations. The distribution of ^{131}I among the serum protein components was studied by electrophoresis.

At a high concentration of triiodothyronine, 5·6 μg. per ml., thyroxine-^{131}I was displaced from the α-globulin and became attached to albumin. The concentration required to produce this displacement was greater than that required by thyroxine. Of the other analogues tested only D-thyroxine had a binding intensity as great as that of L-thyroxine. The results obtained with D-thyroxine, which binds strongly to thyroid-binding protein but has little or no metabolic activity, and L-triiodothyronine, which binds relatively weakly but has strong metabolic effects, suggests that the molecular features responsible for binding to protein are different from those concerned with metabolic activity.

TURCHETTO, E., INFANTE, R. and SECHI, A. M. Influenza della tiroxina sull'attività lipotropa del metionina. [**Effect of thyroxine on the lipotropic activity of methionine.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 1251–1252. [Ist. Chim. Biol., Univ. Bologna.]

Six groups of 5 rats weighing about 180 g. were given a diet to produce fatty liver, including, per cent., casein 10, fats 27 and cholesterol 0·5. One group received 500 μg. thyroxine daily, and one had no addition. The other 4 groups all received 50 mg. methionine daily, alone or with 150 or 300 or 500 μg. thyroxine. The mean total lipid content of the liver in g. per 100 g. fresh tissue ranged from 12·8 to 14·1 in all the groups except those given methionine with the 2 largest doses of thyroxine, in which the values were 6·2 and 6·1. Large doses of thyroxine increased the lipotropic action of an amount of methionine otherwise insufficient.—E. M. Hume.

619

LELOUP, J. and LACHIVER, F. Influence de la teneur en iode du régime sur la biosynthèse des hormones thyroïdiennes. [**Effect of the iodine content of the diet on the biosynthesis of thyroid hormones.**] *C.R. Acad. Sci.*, 1955, **241,** 509–511.

Forty-eight adult rats of both sexes were maintained on a diet containing 10 μg. I per kg., with vegetables twice a week ; 6 adult rats were given the same diet, but drank a solution of KI containing 4 μg. I per ml. for the first 2 months and 20 μg. I per ml. for the third month. After intraperitoneal injections of 30 μC. carrier-free ^{131}I all the rats were killed in pairs 2, 6, 24 or 72 hr. after

injection. By radiochromatographic techniques the percentage of the dose of ^{131}I in total I, monoiodotyrosine, diiodotyrosine, thyroxine and triiodothyronine was estimated.

In the rats given little I the fixation of ^{131}I reached its maximum within 2 hr. after administration and then decreased rapidly. In the rats given KI, fixation of ^{131}I was extremely slow and was still rising at the end of 72 hr. The partition of ^{131}I among the amino-acids of the thyroid varied according to the I content of the diet. In rats given little I, labelled monoiodotyrosine was much more than diiodotyrosine at all the times studied. Labelled thyroxine and triiodothyronine appeared simultaneously within 2 hr., the second nearly always in excess of the first. In the rats given KI, labelled diiodotyrosine exceeded monoiodotyrosine. Synthesis of the hormones was slow; the sum of thyroxine and triiodothyronine was always lower than in the low-iodine group, and thyroxine was synthesised preferentially.

KATSH, S. and WINDSOR, E. **Unusual value for protein-bound iodine in the serum of the opossum.** *Science*, 1955, **121,** 897 – 898. [Kerckhoff Labs. Biol., California Inst. Technol., Pasadena.]

Blood serum from 3 monkeys, 4 rabbits, 15 rats, 5 hamsters, 3 chickens, 5 guineapigs, 3 stallions, 1 sheep and 3 opossums was analysed for protein-bound iodine (PBI) by the method of Barker *et al.* (Abst. 100, Vol. 21). All the animals were in the postprandial state and the season was summer. The serum of the opossum had the lowest PBI content, $0{\cdot}4 \pm 0{\cdot}2$ μg. per cent. The guineapig had the next lowest with $2{\cdot}5 \pm 0{\cdot}5$ and the monkey had the highest, $6{\cdot}0 \pm 0{\cdot}7$ μg. per cent. Previous workers had observed that the opossum has a low body temperature. The occurrence of low body temperature and low PBI in the same animal is discussed. It is suggested that there may be a low level of interaction between pituitary and thyroid, that the tissues are adapted to small amounts of thyroid hormone so that their efficiency is maintained, and that the oxidative metabolic and enzymic rates of the tissues of this marsupial are different from those of other animals.

VASQUEZ MENDOZA, I. Acción de la hormona adrenocorticotrópica sobre la lipidemia. [**Effect of adrenocorticotropic hormone on the blood lipids.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4,** 349–361.

Blood lipids were estimated in 5 groups each of 5 rabbits before and at intervals from 2 to 72 hr. after injection of commercial preparations of adrenocorticotropic hormone. Five males and 5 females received 1·66 mg. Cortrofina per kg. bodyweight intramuscularly and similar groups received 3·32 mg. per kg. The fifth group, of males, received 1·66 mg. ACTHAR per kg. bodyweight.

In all the rabbits there was a fall in blood lipids, greatest 6 hr. after the injection, followed at 24 hr. by a rise to above normal. The magnitude of the changes was independent of the dose or preparation given.—D. Duncan.

625

EMERSON, J. D. **Development of resistance to growth promoting action of anterior pituitary growth hormone.** *Amer. J. Physiol.*, 1955, **181,** 390–394. [Dept. Physiol., Med. Coll. Alabama, Birmingham.]

Subcutaneous injection, once daily for long periods, of purified or crude preparations of pituitary growth hormone of bovine origin into Norway rats produced first rapid growth, followed by reduced growth, then complete or near absence of growth. An increase in the amount of hormone produced renewed growth, followed by flattening of the growth curve at a higher level. The loss of growth response to a high dose of growth hormone did not involve the development of a response to the diabetogenic action of the hormone.

Testosterone ed eliminazione dei cataboliti purinici nel ratto a dieta aproteica con solo apporto di glicina. [**3. Testosterone and the elimination of purine catabolites in rats having a diet without protein and with glycine only.**] Influenza della follicolina sull'escrezione urinaria dei cataboliti purinici in ratti tenuti a dieta aproteica con solo apporto di glicina. [**Effect of folliculin on the urinary excretion of purine metabolites in rats maintained on a diet without protein and with glycine only.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 1207–1208; 1345–1346. [Ist. Clin. Med., Univ. Genoa.]

Ten rats weighing from 150 to 200 g. received a diet of potato starch, palmitic acid and Osborne and Mendel salt mixture, with adequate vitamins. Uric acid and allantoin were estimated in 24-hr. urine before and after a dose of glycine by mouth. After a pause, 5 mg. testosterone propionate per kg. bodyweight was given and the test was repeated. The amounts of uric acid and allantoin in the urine were greater after glycine, but the increase was less with testosterone than without.

In a similar experiment 10 mg. oestradiol benzoate per kg. bodyweight was injected instead of testosterone propionate. The amount of uric acid and of allantoin was greater after administration of glycine, slightly greater after oestradiol and greatest after both.—E. M. Hume.

ENERGY EXCHANGE AND SPECIFIC DYNAMIC ACTION

629

BANERJEE, S. and SEN, R. **Determination of the surface area of the body of Indians.** *J. Appl. Physiol.*, 1955, **7**, 585–588. [Dept. Physiol., Presidency Coll., Calcutta.]

The Du Bois formulae for the calculation of body surface area, either from height and weight or from linear measurements of different parts of the body, were based on measurements of surface area of 9 subjects. The present authors have made careful measurements of surface area on 15 men selected from the students and staff of the Department of Physiology at the Presidency College, Calcutta. The results were consistently higher than the values predicted from either the weight : height formula or the linear formula of Du Bois, and it is concluded that the formulae require modification for use on Indian adults, whose physique differs slightly from that of Americans. New constants have accordingly been calculated for all the Du Bois equations, but it is suggested that the amended weight : height formula should be used rather than the amended linear formula.—I. McDonald.

EDHOLM, O. G., FLETCHER, J. G., WIDDOWSON, E. M. and MCCANCE, R. A. **The energy expenditure and food intake of individual men.** *Brit. J. Nutrition*, 1955, **9**, 286–300. [Div. Human Physiol., Nat. Inst. Med. Res., London.]

In continuation of earlier work (see Abst. 5092, Vol. 24) more intensive study was made for 14 days under similar conditions of 12 cadets for whom mean measurements were, age, 19 years 5½ months, weight 68 kg., height 178 cm. and surface area 1·84 sq. m. Diet surveys were by weighing food and plate waste. Diaries were kept and energy exchange measurements were made for many of the activities.

The average daily intakes, which did not differ greatly from the earlier findings, were 3432 Cal., 99 g. protein, 123 g. fat, 488 g. carbohydrate, 1·14 g. Ca and 21·0 mg. Fe. The means for the cost in Cal. per min. of the different activities were, lying 1·48, sitting 1·60, standing 1·82, marching at 3·4 miles per hr. 6·03, running " at the double " 11·67, stair-climbing 10·30, dressing 4·00, and during kit cleaning, ironing 4·20, polishing 2·40 and rifle cleaning 2·70. Data are given also for sporting activities. The difference in the efficiency with which any two individuals might perform the same task was great.

Each subject's daily intake and expenditure of energy is tabulated. Although the means for all

subjects for daily intakes and expenditures of energy agreed closely, 3432 and 3416 Cal., respectively, intakes differed widely between individuals and from day to day for the same individual. When intake and expenditure data for the same day were plotted the scatter was wide, but a relation existed between expenditure of energy on a single day and the intake on the second day later.

631

TURNER, D. **The energy cost of some industrial operations.** *Brit. J. Indust. Med.*, 1955, **12,** 237–239. [Nuffield Dept. Occupat. Health, Univ. Manchester.]

Two systems were used to assess the arduousness of 48 industrial operations in 3 factories and 2 government training centres. In the first, a subjective assessment was made by the system of job-analysis; in the second, energy exchange was measured on 287 occasions during work. Operations were grouped in 3 classes as heavy and very heavy, moderate or light by the subjective method and, in the same categories, from the metabolism data at rates 135 to 220 Cal. or more, 90 to 134 Cal., or up to 90 Cal. per sq. m. surface area per hr. Agreement between the two groupings was good and, for practical purposes, it is claimed that for placing workers in occupations suitable to their conditions of health and age, a simple survey by the first method of the jobs common to a particular area would provide adequate information.

IRVING, L., KROG, H. and MONSON, M. **The metabolism of some Alaskan animals in winter and summer.** *Physiol. Zoöl.*, 1955, **28,** 173–185. [Arctic Health Res. Centre, Pub. Health Serv., Dept. Health, Educat. Welfare, Anchorage, Alaska.]

The metabolism of Arctic red fox, Alaska red squirrel, porcupine, brent goose (*Branta bernicla orientalis*) and northwestern crow was studied with an open-circuit apparatus at temperatures ranging from 30° to — 50° C. The basal metabolic rate did not appear to vary with the season, but the extent of insulation by fur or feathers was important in regulating heat. The extent of insulation was the same in summer and winter in the birds and in the squirrel. The fox and the porcupine grew thicker fur in winter.—A. M. Copping.

MINETT, F. C. **Experiments on body-cooling and body-overheating in buffaloes, sheep and goats in India.** *J. Comp. Pathol.*, 1955, **65,** 197–219. [Indian Vet. Res. Inst., Izatnagar.]

Experiments are reported with sheep, buffaloes and goats in which the effects of clipping, body size and coat colour, exposure to sunlight, air currents and cool showers, and drinking or wetting the body during exposure to sunlight on rectal temperature and respiration rate were studied.

In clipped sheep undergoing the same exposure to sunlight as unclipped, rectal temperatures did not rise so high at first, but after 18 days the rise was the same as in the unclipped sheep. Effect of coat colour and body size was not clearly demonstrated with sheep.

Buffaloes and goats, when exposed to sunlight, showed greater rises in temperature when behind a screen than when exposed to the breeze. In another test with buffaloes 3 groups were exposed to the sun either without water, or allowed to drink every 2 hr., or with their coats wetted every 2 hr., and 1 was kept in the shade. The air temperature in the shade was as high as it was in the sun. Drinking or wetting did not prevent the animals from reaching the same maximum temperatures as the untreated animals exposed to the sun, though there was a temporary drop in temperature at each wetting. The animals in the shade had consistently lower temperatures than those in the sun. Respiration rates were also

higher in the sun, and were temporarily reduced by wetting. Small buffaloes in each group had higher temperatures than large buffaloes.

Goats were cooled by artificial showers and later exposed to sunlight. Smaller goats showed greater temperature changes than larger. The rise caused by sunlight was greater in black goats than in white. The fall in temperature when they were cooled by showers was not affected by the colour of the coat.—T. D. Bell.

638

BLIGH, J. **Comparison of rectal and deep body temperature in the calf.** *Nature*, 1955, **176**, 402–403. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

It was considered that the temperature of blood leaving the left side of the heart was a good indication of deep body temperature. The technique for measuring this temperature in calves is described. Ayrshire bull calves 4 to 6 months old were kept in climatic chambers up to 6 hr. at 20°, 30° and 40° C. with low humidity and at 35° and 40° C. with high humidity. Deep body temperatures and rectal temperatures were measured every 5 min.

Under any but the most adverse conditions the rectal temperature, though slightly higher than the deep body temperature, accurately reflected the changes in it, and could be used satisfactorily in environmental studies.—T. D. Bell.

ABELIN, I. and GOLDSTEIN, M. Über die Mitbeteiligung des Adrenalin und seiner Derivate an der spezifisch-dynamischen Eiweisswirkung beim Menschen. [**The part played by adrenaline and its derivatives in the specific dynamic action of protein in man.**] *Biochem. Ztschr.*, 1955, **327**, 72–84. [Med. Chem. Inst., Univ. Berne.] English summary.

The subjects were 4 students aged from 23 to 26 years. On the day of experiment the first morning urine was discarded, but urine passed in the 3 hr. after a light breakfast was collected and analysed. The subjects then took a meal of grilled lean meat and urine was again collected for 9 hr. Adrenaline and noradrenaline, free and bound to sulphate or glucuronate, were estimated as well as urea.

Free adrenaline was often absent before and sometimes after the meat meal, but reached a peak either in the first or the second 3 hr. The mean concentration before the meal was 0·9 μg. [presumably per 100 ml.]. There was always free noradrenaline; the mean initial concentration was 36·7 μg. The increase was relatively less after the meal. The behaviour of bound adrenaline and noradrenaline resembled that of the free forms.

It is suggested that increased production of adrenaline may be concerned in the specific dynamic action of proteins.—D. Duncan.

GOTO, Y. **Significance of the two-dose glucose tolerance test. Criticism of the Staub effect.** *Metabolism*, 1955, **4**, 323–332. [Med. Clin., Sch. Med., Tohoku Univ., Sendai, Japan.]

Patients with severe or mild diabetes or without diabetes and a healthy adult were the subjects of single and double oral glucose tolerance tests. A theoretical double blood sugar curve was constructed after the single test by subtracting the fasting value from the values found $\frac{1}{2}$, 1, $1\frac{1}{2}$ and 2 hr. after the dose and then adding the differences to the values recorded $2\frac{1}{2}$, 3, $3\frac{1}{2}$ and 4 hr. after the dose. This calculated double curve was then compared with one recorded after a double test. The calculated and measured curves were usually so similar that the Staub effect is thought to be without significance. The lower peak sometimes seen after the second dose is ascribed to the hypoglycaemia resulting from the first.—D. Duncan.

PEDEN, J. C. (Jr.), RILEY, J. S., BOND, L. and ELMAN, R. **Blood sugar levels following intravenous infusion of glucose and fructose in adults.** *Metabolism*, 1955, **4**, 318–322. [Surg. Metabol. Div., Homer G. Phillips Hosp., St. Louis, Mo.]

Six normal adults received in 90 min. an intravenous infusion of 1000 ml. of 10 per cent. glucose in water, and next day a similar infusion of fructose. Six others received the fructose before the glucose. Total reducing sugar in blood was estimated before and for 3 hr. after the infusion.

At the end of infusion blood sugar was significantly higher after glucose than after fructose, means 215·0 and 152·5 mg. per cent., respectively, but 1, 2 and 3 hr. later the values were higher after fructose in most subjects. Only in the 3 oldest subjects, aged from 44 to 58 years, were blood sugar values above 62 mg. per cent. an hour after the end of glucose infusion, and higher than after fructose. There was always a considerable drop in blood sugar, on the average to 19·3 mg. per cent. below fasting values, after glucose, but never after fructose. One subject developed clinical manifestations of hypoglycaemia after glucose.

The clinical value of fructose infusion is discussed.

ORSINI, M. and MORRICONE, A. Comportamento della glicemia dinamica alimentare dopo carico di differenti zuccheri prima e dopo somministrazione prolungata di lattosio. [**Behaviour of blood sugar curves after oral doses of different sugars before and after prolonged administration of lactose.**] *Arch. ital. Pediat. Puericolt*, 1955, **17**, 298–323. [Clin. Pediat., Univ. Rome.] French, English and German summaries.

The subjects were 17 normal children and 1 with diabetes, all between 3 and 12 years old. Blood sugar curves were studied after single test doses of glucose, galactose, fructose and lactose given by mouth, and these tests were repeated after 20 days in which all sugar was eliminated from the diet except 20 g. lactose twice daily. All test doses were of 2 g. sugar per kg. bodyweight, given after a fast of 8 hr., and with at least a week between successive tests.

In the healthy children all the sugars gave on the average much lower blood sugar peaks or none, and earlier and greater falls to below the initial level, after the lactose period than before it. After the lactose period one child responded to the lactose test with an immediate fall in blood sugar and clinical signs of hypoglycaemia. After the lactose period the diabetic child had a higher blood sugar peak after a glucose test, followed by a greater hypoglycaemic reaction. To galactose and lactose tests the responses were much like those of the normal children in shape, although the blood sugar was generally higher and the hypoglycaemic reaction greater.

It is concluded that continuous administration of lactose increases sugar tolerance. The diabetic child was given lactose for longer than the others and left the clinic on a lower maintenance dose of insulin than before.—D. Duncan.

647

SAUERWEIN, E. Über den Einfluss von Zucker und Honig auf die vegetative Tonuslage des gesunden Menschen. [**Effect of sugar and of honey on the vegetative tone of healthy persons.** *Deutsch. med. Wochenschr.*, 1955, **80**, 968–970. [Sportphysiol. Abt., Sporthochsch., Cologne.]

Systolic blood pressure was continuously recorded in healthy subjects of both sexes subjected to stimulation of the labyrinth by rotation (10 turns in 20 sec.) before and after intravenous injection of from 10 to 25 ml. of a 20 or 40 per cent. solution of honey, or 20 ml. of a 14 per cent. solution of a mixture of mono- and disaccharides or the same of dextrose. The reaction was reversed by honey in 9 out of 27 subjects, always from cholinergic (*i.e.*, rise in systolic blood pressure) to adrenergic, and in 11 others the change was in the same direction but did not amount to a reversal; in 6, however, an adrenergic reaction was weakened or a cholinergic strengthened; in 1, honey had no effect. The sugar mixture, on the other hand, suppressed or diminished blood pressure changes in 14 of 25 subjects. With dextrose the results were inconclusive.

The results are discussed; it is considered that the change in vegetative tone produced by honey injections resembles that produced by physical training, and it is suggested that this may have had something to do with the improved performance of rats in a swimming test reported by Krämer (*Ztschr. klin. Med.*, 1950, **146**, 543). The

sugar mixture, on the other hand, is regarded as providing a non-specific stimulus.—W. M. Deans.

648

CONSTAM, G. R. and SCHMID, H. Ist der Genuss von Honig Zuckerkranken zuträglich? [**Can diabetics tolerate honey?**] *Schweiz. med. Wochenschr.*, 1955, **85,** 282–283. [Diabetikerberatungstelle, Med. Poliklin., Univ. Zürich.]

Some reports have suggested that honey does not affect the blood sugar. When 40 g. honey was eaten at breakfast by a normal subject there was a greater rise in blood sugar in the 90 min. after the meal than with a similar breakfast and no honey. In 3 of 4 diabetic subjects tested after breakfast, 30 or 40 g. honey caused higher blood sugar and glycosuria. It is recommended that diabetics should regard honey as sugar, and that expectorant mixtures for diabetics should not contain honey.—A. M. Copping.

GOLDSCHMIDT, S., BURKERT, H., GLOXHUBER, C., GRAMSS, M., GRAMSS, R., and ANDERS, C. Über die Wirkung von Honig- und Zuckerlösungen auf den Blutzuckerspiegel von Kaninchen bei intravenöser Dauerinfusion. [**Effect of honey and sugar solutions on the blood sugar of rabbits after continuous intravenous infusion.**] *Hoppe-Seyler's Ztschr.*, 1955, **300,** 201–210. [Org. Chem. Inst., Tech. Hochsch., Munich.]

Rabbits narcotised with urethane received intravenous infusions of solutions of glucose, invert sugar, honey or inactivated honey in which the acetylcholine was destroyed.

Honey containing 2·5 μg. acetylcholine per g., infused at 4 mg. per kg. bodyweight per min., caused a steep fall in blood sugar. Invert sugar raised the blood sugar, but inactivated honey produced only a slight and transient increase followed by a fall. A similar slight increase and a greater fall were produced by fructose, and fructose at 10 mg. per kg. per min. accompanied by acetylcholine and choline reproduced the sharp fall caused by honey at 4 mg. per kg. per min. Honey or fructose alone at 10 mg. per kg. per min. caused a rise instead of a fall in blood sugar.

It is concluded that acetylcholine reduces the blood sugar value, but large infusions of honey flood the blood with sugar to an extent which masks the effect of acetylcholine.—D. Duncan.

650

CARSON, M. J. and KOCH, R. **Clinical studies with glucagon in children.** *J. Pediat.*, 1955, **47,** 161–170. [Dept. Paediat., Sch. Med., Univ. S. California, Los Angeles.]

In 16 normal children the increase in blood sugar in response to glucagon, 20 μg. per kg., ranged from 22 to 68, average 54 mg. per cent. after 30 min. Responses of this magnitude were obtained in 4 children with spontaneous hypoglycaemia, in only 3 of 8 with liver disease and in 3 of 6 with glycogen storage disease. In normal children doubling the dose of glucagon did not increase the response, but simultaneous administration of adrenaline both increased and prolonged it. When given with insulin, glucagon counteracted the hypoglycaemic effect.—F. C. Aitken.

KOLB, F. O., DE LALLA, O. F. and GOFMAN, J. W. **The hyperlipemias in disorders of carbohydrate metabolism: serial lipoprotein studies in diabetic acidosis with xanthomatosis and in glycogen storage disease.** *Metabolism*, 1955, **4,** 310–317. [Metabol. Unit, Univ. California Sch. Med., San Francisco.]

Lipoproteins were studied with the ultracentrifuge for 2½ years in a 37-year-old acromegalic woman with uncontrolled diabetes and xanthomata and in 2 young men with glycogen storage disease complicated by a high level of uric acid in the blood and by gout. In the acromegalic woman, large amounts of Sf 20 to 100 and Sf 100 to 400 lipoproteins were found; control of the diabetes improved lipoprotein transport. The serum lipoprotein pattern was similar in glycogen storage disease to that in diabetic acidosis, and it is suggested that high blood sugar itself is not a cause of the disordered lipoprotein transport, but that defective utilisation of carbohydrates may be involved.—G. A. Garton.

MORI REVOREDO, V. Correlación gluco-lipídica en la diabetes. [**Correlation between blood sugar and lipids in diabetes.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4,** 284–291.

Blood sugar and lipids were estimated on from 1 to 6 occasions in 21 patients of both sexes, with diabetes of different grades of severity.

According to Mata (*Crón. Méd., Lima*, 1948, **45,** 113), the " equilibrium " value for blood fat should be 5 times the blood sugar in mg. per 100 ml. On this basis there was no lipid deficit in mild diabetes, but in more severely affected patients the lipid deficit increased with the blood sugar.

BAXTER, C. F., KLEIBER, M. and BLACK, A. L. **Glucose metabolism in the lactating dairy cow.**

Biochim. biophys. Acta, 1955, **17**, 354–361. [Dept. Animal Husb., Univ. California, Davis.] French and German summaries.

A Jersey cow 6 years old, weighing 457 kg. and producing 10 kg. milk daily, received by intravenous injection 2·9 mC. glucose uniformly labelled with ^{14}C. Respired air was collected for measurement of $^{14}CO_2$, and in 2 days after the injection 11 blood samples were taken for estimation of blood and plasma glucose and haematocrit. Plasma volume was estimated with Evans Blue. Plasma and milk glucose were isolated as glucosazones for estimation of specific activity.

The total body glucose pool was calculated to be 62·4 g. and the turnover from this pool 70·4 g. per hr. These may be maximum values. The cow's plasma volume was 20·3 litres and the total plasma glucose content was 12·2 g.

In 48 hr. nearly all the ^{14}C injected had left the cow's body, 56·9 per cent. in the main organic constituents of milk and 40·3 per cent. in respired CO_2. Urine, faeces, rumen gases and minor constituents of milk probably contained most of the other 2·8 per cent. It is calculated that only from 8·8 to 11·5 per cent. of the total CO_2 respired came from oxidation of glucose.

It is concluded that in the energy metabolism of the cow glucose is of less importance than it is in the non-ruminant species which have been studied.

FÁBRY, P. Vliv složeni potravy na denní rytmické kolísání glycidovych reserv. [**The influence of diet on the daily rhythm of carbohydrate reserves.**] *Čsl. fysiol.*, 1955, **4**, No. 1, 1–6. [Dept. Physiol., Res. Inst. Human Nutrit., Prague.]

Rats on a diet without carbohydrate showed an increase of liver glycogen 14 to 16 hr. after food. The blood sugar in these animals varied inversely with liver glycogen.—A. Jančařík (Czechoslovakia).

656

FÁBRY, P. Studie o adaptaci přeměny látkové. [**Studies on the adaptation of metabolism.**] *Čsl. fysiol.*, 1955, **4**, No. 1, 7–9. [Dept. Physiol., Res. Inst. Human Nutrit., Prague.]

Rats on a normal mixed diet were accustomed to long-term and graduated fasting. They formed more glycogen in the liver than control animals. After 16 hr. of fasting they liberated the same quantity of liver glycogen as control rats.

M. Prokšová (Czechoslovakia).

657

LASZT, L. Analyse von Leberglykogenen normaler und diabetischer Ratten mit der Ultrazentrifuge. [**Analysis of the liver glycogens of normal and diabetic rats by the ultracentrifuge.**] *Biochem. Ztschr.*, 1955, **327**, 32–38. [Physiol. Inst., Univ. Fribourg, Switzerland.]

An earlier finding (*Experientia*, 1954, **10**, 302) that the liver glycogen of diabetic rats differed from the normal prompted further investigation with the ultracentrifuge. The sedimentation diagram of liver glycogen from normal rats fasted for 24 hr. had a single peak; that from similar rats given a mixed feed 3½ hr. before liver was taken had a second peak, indicating the presence of a second glycogen of greater molecular weight. The glycogens could be separated by fractional precipitation with glacial acetic acid. There was no second peak in the sedimentation diagrams from fasted or fed diabetic rats, which differed little, but there was evidence of a small residual fraction, the nature of which is not clear.—W. M. Deans.

LEONARD, H. B., BERRY, M. E. and SCHUCK, C. **Effect of alloxan in rats fed cornstarch-, sucrose-, and lactose-diets.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 708–710. [Dept. Foods Nutrit., Purdue Univ., Lafayette, Ind.]

Groups of 3 to 5 rats were given, to appetite, diets of casein 18, salt mixture 4, Crisco 10, cod liver oil 5, dried brewer's yeast 10 and carbohydrate 53 per cent., the carbohydrate consisting of maize starch, sucrose or lactose, for 14 to 20 days. They were then starved for 48 hr. and injected with 175 mg. and, later, 150 mg. per kg. bodyweight of a 2½ per cent. solution of alloxan monohydrate. The rats on the maize starch and sucrose diets grew at a normal rate before the injection and were healthy and vigorous, but the rats on the lactose diet were retarded in growth and poorly nourished, so a fourth group of rats was given the maize starch diet at the restricted level of 5 to 7 g. daily for 2 weeks before the alloxan, in an attempt to produce a low nutritional state comparable to that of the rats on the lactose diet.

The highest susceptibility to the diabetogenic effects of alloxan occurred among the rats given the maize starch diets to appetite; susceptibility was slightly less among the rats on the sucrose diet and was lowest among the rats on the lactose diet. The restriction of intake of the maize starch diet reduced susceptibility; 4 out of 12 rats became diabetic, compared with 16 out of 19 given maize starch to appetite, 9 out of 12 given sucrose and 3 out of 12 given lactose.—G. F. Garton.

SEEBERG, V. P., MCQUARRIE, E. B. and SECOR, C. C. **Metabolism of intravenously-infused sorbitol.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 303–305. [Res. Div., Cutter Labs., Berkeley, Calif.]

Rabbits received sorbitol in 10 per cent. solution by intravenous infusion at the rate of 1 g. per kg. bodyweight hourly for 1½ hr. Blood samples were taken from the femoral artery. Control rabbits received saline.

During infusion of sorbitol there was a prompt rise in blood fructose, which reached about 50 mg. per 100 ml. at the end of the infusion and thereafter fell rapidly. There was no significant change in blood glucose during the first hour of infusion, but an erratic rise then began and continued for some time after the infusion ended. It is concluded that there was secondary conversion of fructose to glucose. Even when sorbitol was given at the slower rate of 0·33 g. per kg. per hr., some sorbitol was recovered from the urine.

PETERSEN, J. C., STRIPE, M. C. and HIMWICH, W. A. **Metabolic effects of *l*-glutamic acid and of glycine.** *Amer. J. Physiol.*, 1955, **181,** 519–522. [Thudichum Psychiat. Res. Lab., Galesburg State Res. Hosp., Ill.]

Subcutaneous injection of sodium glutamate or glycine at *p*H 7·0, at 2 g. per kg. bodyweight, produced very high blood sugar values in rabbits. Pyruvic acid values fell in the blood of rabbits given glutamate, and α-ketoglutarate rose. Glutamate protected rabbits against the fall in blood sugar caused by insulin, without producing high blood sugar. Glycine had no protective effect. Liver glycogen was decreased by glutamate or glycine, whatever the blood sugar level.

GAYER, J. and KLINGMÜLLER, V. Untersuchungen über den Stoffwechsel der L(+)-Glutaminsäure. 3. Wirkungen von L(+)-Glutaminsäuregaben auf den Kohlenhydratstoffwechsel. [**Experiments on the metabolism of L(+)-glutamic acid. 3. Effect of L(+)-glutamic acid intake on carbohydrate metabolism.**] *Hoppe-Seyler's Ztschr.*, 1955, **301,** 269–284. [Physiol. Chem. Inst., Univ. Hamburg.] English summary.

Blood sugar curves were studied in 6 rabbits after test doses of glucose by mouth, alone and with glutamic acid. The glutamic acid reduced the rise in blood sugar. In 4 adult human subjects no such effect was found. Glutamic acid also reduced the fall in blood sugar after insulin in rabbits and prevented insulin shock so long as it was given 30 min. before the insulin, but not when it was given 60 min. before. In alloxan-diabetic rabbits glutamic acid given intravenously caused a large rise in blood sugar, but this was prevented by the adrenaline antagonist Hydergin.

In rats given glutamate intraperitoneally and killed 2 hr. after the third injection the liver glycogen was significantly below that of control rats given saline. This was not prevented by Hydergin, which caused a fall in blood sugar, or by removal of the adrenals.

In rats deprived of pyridoxine the injection of glutamate did not significantly affect liver glycogen.

It is concluded that mobilisation of liver glycogen by glutamic acid depends on an intact transaminase system, but not on adrenaline.

Recherche Sci., 16, Rue de l'Estrapade, Paris.]

Contents of the caecum or the large intestine of rats were cultured in meat broth in a study of the fermentation of glucose and other carbohydrates.

Glucose, maltose and sucrose, the " energetic " carbohydrates, and also lactose, were readily fermented by intestinal bacteria. Galactose, D-xylose and L-arabinose were fairly well utilised, D-arabinose but poorly and L-xylose not at all. Even intestinal contents from a rat adapted to a diet containing L-xylose did not attack this sugar.

Despite their resistance to bacterial attack, both L-xylose and D-arabinose are well utilised by rats and extremely active in increasing the utilisation of Ca (see Abst. 2213, Vol. 25). It is concluded that their effects are metabolic and are not mediated by the intestinal flora.—D. Duncan.

667

FOURNIER, P., DUPUIS, Y. and SUSBIELLE, H. Les propriétés structurales du mannose. [**Structural properties of mannose.**] *C.R. Soc. Biol.*, 1955, **149**, 645–648. [Lab. Physiol. Nutrit., Hautes-Études, Paris.]

The effect of 6 or 12 per cent. mannose on utilisation of Ca by young rats was compared with the effects of starch or of 12 per cent. fructose or lactose, by the method described in Abst. 745, Vol. 25.

Mannose at both levels favoured the utilisation of Ca and at 12 per cent. it was much more effective than lactose ; the coefficient of utilisation of Ca was 21 per cent. with starch, 36 per cent. with lactose and 48·5 per cent. with mannose. Mannose is therefore classed as a " structural " carbohydrate (see Absts. 2213, 5195, Vol. 25).—D. Duncan.

TERRAZOS C., J. A. Variaciones de la fosforemia por acción de la insulina. [**Variations in blood phosphorus caused by insulin.**] *An. Fac. Farm. Bioquim., Lima*, 1953, **4**, 312–321.

Two groups of 8 rabbits were fed for 8 days before the experiment mainly on alfalfa. The rabbits, which weighed from 1500 to 2500 g., received subcutaneously either 1 or 4 units of insulin per kg. bodyweight ; the larger dose produced coma in each rabbit, and dextrose was given intravenously when necessary. Blood serum inorganic P was estimated before and for 7 or 24 hr. after the injection of insulin. The normal value was usually regained within 7 hr.

The initial serum inorganic P values lay between 2·99 and 4·99, mean 4·13 mg. per 100 ml. The concentration fell after insulin, usually being lowest 3 hr. after the injection. There was no relation between the magnitude of the fall and the dose of insulin. The initial and lowest mean values in the 2 groups were with the smaller dose 4·06 and 2·11, and with the larger 4·20 and 2·05 mg. per 100 ml.—D. Duncan.

669

SETCHELL, B. P. and MCCLYMONT, G. L. **Blood inorganic phosphorus and serum potassium in insulin hypoglycaemia in the sheep.** *Austral. J. Agric. Res.*, 1955, **6**, 589–594. [Nutrit. Res. Lab., Vet. Res. Stat., Glenfield, N.S.W.]

Eighteen ewes, non-pregnant or in early pregnancy, were given water but no food for 5 days. Six then received insulin, 10 units per kg. bodyweight subcutaneously, 6 the same dose intravenously, and 6 no insulin. Blood glucose and inorganic P and serum K were estimated before and for 60 hr. after the injections.

Blood glucose fell after insulin given by either route ; a secondary rise occurred more than 24 hr. after intravenous insulin and had subsided within 40 hr. After subcutaneous insulin the initial fall persisted longer ; 4 sheep died after 24 hr. and only 1 of the remainder showed the secondary rise.

Serum K in both groups given insulin fell with the fall in blood sugar and recovered more quickly in the intravenous than in the subcutaneous group. Inorganic P also fell with the blood sugar in both groups, but it remained low until after blood sugar and K had risen. All the falls were slower than in man.—D. Duncan.

CASTRO, V., TERRANOVA, T. and FEO, F. Sulle modificazioni biochimiche indotte dalla insulina. 1. Consumo di ossigeno da parte di omogenati di organi, in presenza di substrati diversi. [**Biochemical changes caused by insulin. 1. Oxygeen onsumption by homogenates of organs in the presence of different substrates.**]

CASTRO, V. and TERRANOVA, T. 2. Comportamento degli aminoacidi liberi negli organi. [**2. Behaviour of the free amino-acids in the organs.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 906–909 ; 909–911. [Ist. Fisiol., Univ. Palermo.]

1. Injections of 4 I.U. insulin were given to 12 rats weighing from 120 to 140 g., which had fasted for 24 hr. After 90 min. they were killed and oxygen consumption was measured in homogenates from liver, lungs, kidneys, spleen, brain and muscle, and in homogenates from tissues of 12 similar rats not given insulin. Oxygen consumption was measured in presence of *dl*-alanine, or Na succinate, or glucose, or with no addition. With no addition or with *dl*-alanine, oxygen consumption was greater for all the tissues of rats given insulin. With succinate, oxygen consumption was greater in the kidneys and spleen of rats given

insulin, and less in the other tissues. With glucose, oxygen consumption was greater in the liver, kidneys and muscle of rats given insulin and less in the other tissues.

2. Thirteen free amino-acids were estimated by paper chromatography in the heart and the same 6 tissues of 2 groups of rats given and not given insulin as just described. In general, the content of each amino-acid was greater in the tissues of the animals given insulin. This was true for every amino-acid tested in brain and muscle, and for all except aspartic acid in liver, but in the other tissues there was no regular difference.

Samples of pasteurised fat-free human milk or skimmed cow's milk were introduced into the stomachs of premature and full-term infants and the degree of digestion was estimated as percentage of amino-N in total N. In 28 experiments on 17 children at ages ranging from 6 to 44 days there was little digestion of human milk protein and good digestion of cow's milk protein. There was no correlation between degree of hydrolysis of cow's milk protein and weight of infant at birth or at time of the test.—F. C. Aitken.

MURTHY, H. B. N., REDDY, S. K., SWAMINATHAN, M. and SUBRAHMANYAN, V. **The metabolism of nitrogen, calcium and phosphorus in under-nourished children. 1. Adaptation to low intake of calories, protein, calcium and phosphorus.**

SUR, G., REDDY, S. K., SWAMINATHAN, M. and SUBRAHMANYAN, V. **2. The effect of supplementary groundnut-milk curds on the metabolism of nitrogen, calcium and phosphorus.** *Brit. J. Nutrition*, 1955, **9**, 203–209; 210–215. [Central Food Technol. Res. Inst., Mysore, India.]

1. The 5 subjects were girls aged from 7 to 9 years, living in an orphanage. During the experiment they ate the usual poor rice diet and their average energy intake was 1010 Cal., 40 per cent. more than the computed basal metabolism. Mean daily N intake and retention were 3·0 and 0·28 g., respectively, and all subjects were in positive balance. Corresponding values for Ca were 200 and 23 mg., with 1 subject in negative balance, and for P 567 and 62 mg., with 1 subject in negative balance.

2. The subjects of study were 6 comparable pairs of girls aged from 8 to 11 years. One of each pair received a daily supplement of 12 oz. groundnut milk curds to the basal poor rice diet. In the unsupplemented and supplemented groups mean daily intakes of total N were 3·60 and 5·16 g. and mean retentions of N were 0·28 and 0·73 g., respectively. Corresponding values were Ca intake 382 and 676 mg., Ca retention 73 and 233 mg., P intake 546 and 766 mg., P retention 57 and 116 mg. The increases in retention of N and P with the supplement were significant.—F. C. Aitken.

SHARPENAK, A. E. and EREMIN, G. P. Vliyanie rezhima pitaniya na ispol'zovanie belkov organizmom. [**The influence of feeding regimen on protein utilisation by the organism.**] *Vop. Pitan.*, 1955, **14**, No. 4, 7–12. [Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

In human subjects and dogs the effects on protein utilisation of the number of meals over which a constant amount of food was equally divided, and the effect of giving the bulk of the food in the morning, during the day, or in the evening were studied.

All alterations in feeding regimen caused a temporary fall in protein utilisation. Utilisation was best when food was given 4 times daily. In dogs, giving 60 per cent. of the food in the evening caused a decrease in protein utilisation.

679

BRANDT, J. L., CASTLEMAN, L., RUSKIN, H. D., GREENWALD, J. and KELLY, J. J. (Jr.) (with JONES, A.) **The effect of oral protein and glucose feeding on splanchnic blood flow and oxygen utilization in normal and cirrhotic subjects.** *J. Clin. Invest.*, 1955, **34,** 1017–1025. [Dept. Med., Coll. Med., State Univ. New York.]

The subjects were 14 convalescent patients considered to have normal liver function and 26 with cirrhosis, of whom 21 had a history of alcoholism and 5 one of acute hepatitis in earlier years. Splanchnic blood flow was estimated with bromosulphalein by a method described, and oxygen consumption was calculated from oxygen concentrations in artery and hepatic vein. Estimations were made before and after fluid meals containing either 60 g. protein or 100 g. glucose.

In normal and cirrhotic subjects the protein meal produced increases in splanchnic blood flow, arterio-venous oxygen difference and splanchnic oxygen consumption, but the changes were somewhat less in the cirrhotic subjects. Glucose produced little change in these values. Under fasting conditions the livers of icteric, cirrhotic subjects extracted much less oxygen per unit of blood than the livers of normal or of non-icteric, cirrhotic subjects, but there was a sharp increase in oxygen extraction after a protein meal. In 8 cirrhotic subjects amino-N concentration in peripheral blood and in the hepatic vein after the protein meal were higher than those in 2 normal subjects.

PHANSALKAR, S. V. and PATWARDHAN, V. N. **Utilization of animal and vegetable proteins: urinary nitrogen excretion in absorptive and early post-absorptive phases.** *Indian J. Med. Res.*, 1955, **43,** 265–276. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Four healthy men were given test meals containing protein from an animal or a vegetable source and urine samples were collected hourly for estimation of N. Twelve observations were made on 7 healthy men given similar animal or vegetable protein meals; urine N and blood sugar were estimated immediately after and 1 and 1½ hr. after the meal and then every hour for 7½ hr. As sago formed the only source of carbohydrate in the animal-protein meals, 2 healthy men were given test meals in which the carbohydrate was derived from either sago or wheat starch; blood sugar was estimated.

From 11 to 35 per cent. more N was excreted within 8 hr. after the animal-protein test meal than after the vegetable protein, although the intake of protein, fat and energy was the same. Urine volume was directly correlated with urine N; a larger volume of urine was excreted after the animal- than after the vegetable-protein meals. After animal protein, blood sugar rose and fell more quickly than after vegetable protein, although the heights of the peaks were identical.

CHITRE, R. G., NADKARNI, D. S. and MONTEIRO, L. **The effect of protein nutrition on the "urea clearance" in human subjects.** *J. Postgrad. Med., Bombay,* 1955, **1,** 79–96. [Indian Counc. Med. Res. Nutrit. Res. Unit, Seth G.S. Med. Coll., Bombay 12.]

Urea clearance was studied in 100 clinically healthy Indians, 97 men and 3 women, 47 on mixed diet and 53 strict vegetarians. Their ages were from 20 to 38, mean 24 years. Both standard clearance, for 42 subjects, and maximum clearance values, for 58, were lower than those reported for American subjects. The mean values were 36·6 ± 2·80 and 45·6 ± 3·64 ml. per min. [according to the summary, but the tables say 38·4 and 49·0].

From these subjects 10 vegetarians and 10 non-vegetarians were chosen and their protein intakes were calculated from standard tables. The means were 37·25 and 47·7 g. daily. After 3 urea clearance tests on their normal diet their protein intake was raised to 80 to 84 g. daily for a month; the tests were repeated then and again 2 months after return to normal diet.

In both groups when the protein intake was raised the urea clearance rose to values comparable with those reported for Americans. Of the N compounds in blood and urine, only urine urea was increased on the high protein intake. There was no difference between animal and vegetable protein diets in these respects.—D. Duncan.

682

PLOUGH, I. C., FORSYTH, B. T., TESCHAN, P. E. and SBOROV, V. M. **Studies of nitrogen balance in acute viral hepatitis.** *Amer. J. Med. Sci.*, 1955, **230,** 182–189. [Dept. Metabol., Med. Div., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington 12.] Interlingua summary.

Balance of N was studied in 5 patients with viral hepatitis, who had a diet of fixed N content. The extent of liver impairment was measured by serial estimations of bilirubin in serum. No correlation was found between the measurements. It was concluded that in patients with liver disease any beneficial effect of protein results from its eliminating a deficiency already in existence.

R. and FREMONT-SMITH, K. **Biosynthetic determination with radioactive sulphur of turn-over rates of various plasma proteins in normal and cirrhotic man.** *J. Clin. Invest.*, 1955, **34,** 1126–1146. [Dept. Med., Univ. Washington, Seattle.]

Turnover times for total serum proteins, albumin, β_1-lipoprotein, fibrinogen and γ-globulins were measured in normal and cirrhotic human subjects after ^{35}S-labelled cystine given by mouth or infusion of ^{35}S-labelled normal plasma. Transfused labelled plasma protein yielded shorter apparent turnover times than those after oral administration of labelled amino-acid. Fibrinogen and β_1-lipoprotein were much more rapid in turnover of the S label than were albumin, γ-globulins or total serum proteins. After transfusion of labelled plasma, apparent half-life values in the normal subject for fibrinogen and β_1-lipoprotein were on the average 3·5 days, compared with a median of 21·5 days for albumin and 25 days for γ-globulins.

GEIGER, E., EL RAWI, I. and THOMAS, H. V. **Experiments with intermittent feeding of protein to rats.** *J. Nutrition*, 1955, **56,** 273–284. [Dept. Pharmacol., Med. Sch., Univ. S. California, Los Angeles.]

Rats of one group received 5·9 g. of a complete diet daily; a second group received 4 g. of a fat- and protein-free diet for 5 days and for 3 days 9·1 g. of another complete diet; the total food intake in 8 days was the same in both groups. In a second experiment a similar plan was followed using different diets, so that the daily diets of both groups contained equal amounts of carbohydrate and fat, but protein was given intermittently. In the third experiment, on both adult and young rats, the control group received a 12 per cent. casein diet and the experimental group received alternately 4 and 18 per cent. In the first 2 experiments weighed amounts of diet were eaten by the rats and bodyweights were ascertained weekly; in the third the animals received food to appetite and the quantities eaten as well as bodyweights were recorded daily.

In the experiments with low-energy diets growth was slower when feeding was intermittent, although the total protein intake was the same. When food was given to appetite growth was better in the control than in the experimental group. Brief protein restriction did not create a protein hunger which would increase the protein intake when protein-rich diets became available. The experiments indicate that growth and maintenance are best when protein intake is related to the growth and maintenance requirements of the body.

POLEZHAEVA-SHIFMAN, A. S. Vliyanie temperatury vneshnei sredy i razlichnykh kolichestv belka v pishche na ves tela i nekotorye pokazateli obmena veshchestv pecheni v svyazi s problemoi optimal'nogo soderzhaniya belka v ratzione. [**Effect of external environmental temperature and of different amounts of protein in food on bodyweight, and some indications of the metabolism of liver tissue in relation to the problem of optimum content of protein in the diet.**] *Biokhimiya*, 1955. **20,** 57–65. [Minist. Zdravookhran. USSR, Kiev.]

Rats were given a synthetic diet with 20 per cent. casein for 7 or 8 days, starved for 48 hr., then divided into groups which were given different amounts of casein in the diet and were studied at 30° C., 1° to 8° C. and room temperature. After 4 days the animals were killed and bodyweight, liver N and glutathione and xanthine oxidase activity of the liver were recorded.

At high temperatures a diet containing 20 per cent. casein was best, but at low temperatures 40 per cent. casein was more satisfactory. The value of xanthine oxidase estimations in such studies is stressed.—D. W. Taylor.

687

THOMSON, W. S. T. and MUNRO, H. N. **The relationship of carbohydrate metabolism to protein metabolism. 4. The effect of substituting fat for dietary carbohydrate.** *J. Nutrition*, 1955, **56,** 139–150. [Dept. Biochem., Univ. Glasgow.]

See Abst. 726, Vol. 24.

The output of N in the urine of young rats increased for a few days after the isocaloric substitution of olive oil for glucose in the diet. When

fat was included at the expense of glucose in protein-containing diets a much greater increase in urine N occurred than after a similar exchange in diets devoid of protein. The change in N balance which resulted from the isocaloric replacement of glucose by olive oil was of the same order whether the oil was given with the protein of the diet or apart from it. It is suggested that the effect is caused by the removal of carbohydrate from the protein-containing diet and not by an adverse effect of fat and protein together. A linear relation was found between the amount of carbohydrate given along with protein and the N balance of the animal.—G. A. Garton.

TOROPOVA, G. P. Obmen belka v organakh i tkanyakh belykh krys razlichnogo vozrasta. [**Protein turnover in organs and tissues of white rats of different ages.**] *Vop. Pitan.*, 1955, **14,** No. 4, 12–14.

Male rats weighing 50 and 350 g. were given by subcutaneous injection methionine labelled with ^{35}S. They were killed from 30 min. to 48 hr. after the injection and kidney, liver, blood and muscle were analysed.

The absolute uptake of ^{35}S was greatest for kidney tissue and less for liver, blood and muscle in that order. The amounts were greater for young than for adult animals in kidney and muscle, similar in blood and less in liver. The rates of uptake of ^{35}S in both growing and adult rats were high in kidney, liver and blood and reached a peak in 3 to 4 hr. The rate was considerably less in muscle. Subsequent decline in radio-activity was greater for growing than for adult animals in all tissues except muscle.—D. W. Taylor.

689

MAURER, W. and MÜLLER, E. R. Albumine als Vorstufe von Globulinen im normalen Organismus der Ratte. [**Albumin as precursor of globulin in the normal organism of the rat.**] *Biochem. Ztschr.*, 1955, **326,** 474–483. [Klin. Med., Univ. Cologne.]

Torula yeast was grown in a medium containing sulphate labelled with ^{35}S, and the yeast proteins contained amino-acids labelled with sulphur. Rats were given about 100 mg. yeast containing 22 to 25 mC. ^{35}S and 10 hr. later blood was obtained, from which labelled albumin was isolated electrophoretically. Most of the ^{35}S was in cystine, less in methionine. Four rats received injections of labelled albumin, 80, 36, 36 and 4 mg., respectively, and the distribution of ^{35}S in their serum proteins was studied by electrophoresis after 4 and 25 days.

Labelled globulin was found in the serum, and on the fourth day the mean ratio of labelled albumin : labelled globulin was $8{\cdot}4 \pm 0{\cdot}6$ and was independent of the quantity of labelled albumin injected. All the globulin fractions were labelled.

Similar results were obtained when rabbits were given labelled rabbit albumin.

The implications of the results, which suggest that serum albumin is an immediate precursor of globulin, are discussed.—D. Duncan.

690

YOUNG, D. R. and COOK, S. F. **Effect of environmental temperature and dietary protein on urinary nitrogen excretion of rats.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 482–484. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Three groups of 8 male rats were fed to appetite for 3 weeks before and throughout the experiment on a diet of bleached flour 82, Crisco 6·35, sodium caseinate 5·3, salt mixture 4·25, water-soluble vitamins 1·06 and oil-soluble vitamins 1·06 per cent.; 14 kg. of the diet was supplemented with 1 g. α-tocopherol and 6·5 g. choline. The rats were continuously exposed to environmental temperatures of 4° C. ± 0·2, 23° C. ± 1 and 35° C. ± 0·8 for 50 days; measurements of food intake, urine N excretion and bodyweight were made every third day from the tenth to the fiftieth day.

Food intake, total urine N and urea, allantoin and creatine were inversely proportional to the environmental temperature. Excretion of uric acid, ammonia and amino-acids, and creatinine bore no apparent relation to the environmental temperature.—G. F. Garton.

691

KOLFF, W. J. and PAGE, I. H. **Influence of protein diets on development of renoprival hypertension in dogs.** *Amer. J. Physiol.*, 1955, **181,** 580–584. [Res. Div., Cleveland Clin. Found., Cleveland, Ohio.]

The kidneys were removed from 33 dogs under anaesthesia. Some dogs were then overhydrated by filling the peritoneal cavity with 100 ml. per kg. bodyweight daily of an electrolyte solution resembling extracellular fluid. Others were treated with intermittent peritoneal lavage. Some were force-fed with a salt-free diet containing 4 to 6 g. casein per kg. bodyweight daily, vegetable oil and sugar. Others were force-fed with casein, oil and sugar and also received parenterally 16 ml. normal saline solution per kg. bodyweight daily during the first days after nephrectomy; peritoneal lavage was performed 3 or 4 days after nephrectomy. Two dogs were force-fed with dialysed dog chow, groundnut oil and glucose and were maintained for 15 days by peritoneal lavage without overhydration; dogs which vomited were not kept on the diet and were used as controls, and other

controls had peritoneal lavage but were not fed. Sodium levels in plasma or in the equilibrated rinsing fluid were closely followed; none of the dogs showed low blood Na. Serum K levels were all within or close to the normal range.

High blood pressure after nephrectomy was augmented by overhydration, but neither its occurrence nor its severity was altered by daily peritoneal lavage. The high-protein diet caused only a slight increase in severity of high blood pressure, much less than overhydration. The high-protein diets increased the number and severity of medial arteriolar necroses and of focal myocardial necroses compared with lesions in unfed nephrectomised dogs.—G. F. Garton.

DOOLAN, P. D., HARPER, H. A., HUTCHIN, M. E. and SHREEVE, W. W. **Renal clearance of eighteen individual amino acids in human subjects.** *J. Clin. Invest.*, 1955, **34,** 1247–1255. [Metabol. Res. Facility, U.S. Naval Hosp., Oakland, Calif.]

The renal clearances of 18 amino-acids were measured with inulin in 3 normal adult males during fasting and during the infusion of a mixture of amino-acids. Although the amounts of amino-acids re-absorbed and excreted increased during continuous infusion, less than 4 per cent. of that administered was excreted. Histidine, serine, glycine and threonine were less completely re-absorbed than the others.—A. Hepburn.

SCHREIER, K. and KARCH, H. L. Über den Einfluss von chirurgischen Eingriffen auf den Aminosäurenstoffwechsel. (Mit einer Untersuchung der Phenylhydrazinpositiven Corticoide im Urin.) [**The effect of surgical procedures on amino-acid metabolism. (With a study of the phenylhydrazine-positive corticoids in urine.)**] *Langenbecks Arch. klin. Chirurg.*, 1954–55, **280,** 516–535. [Kinderklin., Univ. Heidelberg.]

The 19 patients were from 21 to 72 years old and were operated on for a variety of reasons. Urine amino-N was estimated in all of them before and after operation, total urine N in 10 and serum amino-acids in 5. The excretion of 11 amino-acids was estimated.

In every patient the daily excretion of total and amino-N rose sharply after operation, reaching a peak after 3 or 4 days. The serum amino-acids were usually lower 3 or 4 hr. after operation than before, though in 4 patients out of 5 *iso*leucine and leucine values rose. The increase in amino-N excretion held for all the 11 amino-acids tested and was of the same relative order of magnitude for all, the mean ranging from 243 per cent. for valine to 315 per cent. for leucine. The mean excretion of corticoids rose from about 150 to 330 μg. daily, and the protein loss is attributed to an " alarm reaction " in Selye's sense.—D. Duncan.

ROSE, W. C., COON, M. J., LOCKHART, H. B. and LAMBERT, G. F. **The amino acid requirements of man. 11. The threonine and methionine requirements.** *J. Biol. Chem.*, 1955, **215,** 101–110. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

For part 9 see Abst. 5243, Vol. 25.

The minimum daily amounts of threonine required to maintain N balance in 3 young men on a purified diet were 0·6 and 1·0 g. of the racemic acid and 0·5 g. L-threonine, respectively. D-Threonine had no effect on N balance. A daily intake of 0·5 g. L-threonine was tentatively taken as the minimum requirement of man and 1·0 g. as safe. A daily intake of 2 g. or less DL-threonine maintained positive N balance in 26 young men, of whom 4 received 1·2 g. and 16 received 1·6 g.

Six young men required minimum daily amounts of 0·8, 0·9, 0·9, 0·9, 1·0 and 1·1 g. DL-methionine for N balance. D-Methionine was as effective as L-methionine. A daily intake of 1·1 g. methionine was tentatively taken as the minimum requirement of man and 2·2 g. as safe. A daily intake of 2·2 g. or less maintained positive N balance in 20 subjects, 17 of whom received 2·0 g. or less.—A. Hepburn.

D-Tryptophan ingested by normal adults was shown by paper chromatography to be excreted in the urine, along with appreciable amounts of D-kynurenine and traces of indolepyruvic acid and acetyltryptophan. The addition of iodine produced a reddish-purple precipitate. DL-Tryptophan dissolved in urine or water gave this reaction.

HARPER, A. E., WINJE, M. E., BENTON, D. A. and ELVEHJEM, C. A. **Effect of amino acid supplements on growth and fat deposition in the livers of rats fed polished rice.** *J. Nutrition,* 1955, **56,** 187–198. [Dept. Biochem., Univ. Wisconsin, Madison.]

Rats grew better on a diet containing 90 per cent. rice, providing only 5·9 per cent. protein, than with 7·4 or 7·3 per cent. protein from maize or wheat. Only rats fed on the rice diet had an accumulation of liver fat after 2 weeks and this was much less when casein or other proteins replaced part of the rice. With 0·24 per cent. DL-threonine, 0·4 per cent. L-lysine prevented the accumulation of liver fat, but 0·2 per cent. did not, although it produced better growth. Other amino-acids did not affect fat deposition and did not improve growth when added with lysine and threonine. Only a mixture of all the essential amino-acids gave a further growth response.—A. Hepburn.

HENRIQUES, O. B., HENRIQUES, S. B. and NEUBERGER, A. **Quantitative aspects of glycine metabolism in the rabbit.** *Biochem. J.,* 1955, **60,** 409–424. [Nat. Inst. Med. Res., London, N.W.7.]

The radio-activity of plasma glycine fell sharply during the first 30 min. and slowly from 6 to 18 hr. after the intravenous injection of α-^{14}C-glycine into rabbits. The replacement of all the liver glycine by plasma glycine was estimated to take 15 to 20 min. and was thought to depend on the rate of blood flow. The replacement of muscle glycine took 20 to 25 hr. and the slow equilibration was caused by slow blood flow in muscle and partial permeability. Glutathione had renewal times of 10 to 12 hr. in the liver and 20 hr. in muscle. A rapid conversion of glycine to serine was indicated, and the muscle cell appeared to be more permeable to serine.

It was calculated that about 1·9 g. protein per kg. bodyweight was synthesised daily in the liver. Of this 40 per cent. was related to plasma proteins and the rest to liver proteins.—A. Hepburn.

WIXOM, R. L., PIPKIN, G. E. and DAY, P. L. **Interrelationship of serine and glycine for chick growth.** *J. Nutrition,* 1955, **56,** 409–422. [Dept. Biochem., Univ. Arkansas Sch. Med., Little Rock.]

Glycine, but not extra N in the form of diammonium citrate or alanine, increased the growth rate of 2-week-old chicks fed on a diet containing casein and deficient in glycine. The need for glycine was less in 4-week-old chicks. DL-Serine also improved growth rate. The results suggested a relation between serine and glycine, of which one is required for the young growing chick.

HARPER, A. E., BENTON, D. A. and ELVEHJEM, C. A. **L-Leucine, an isoleucine antagonist in the rat.** *Arch. Biochem. Biophys.,* 1955, **57,** 1–12. [Dept. Biochem., Univ. Wisconsin, Madison.]

The experimental groups were each of 6 rats weighing between 40 and 50 or between 200 and 250 g. The diets contained, per cent., salt mixture 4, maize oil 5, casein 9 or 18 or bloodmeal 18 and sucrose to 100. Diets with 9 per cent. casein contained also 0·1 per cent. DL-tryptophan and 0·3 per cent. DL-methionine, and those with 18 per cent. casein or sucrose contained 0·2 per cent. DL-methionine. All diets contained added vitamin B_1, riboflavin, nicotinic acid, calcium pantothenate, pyridoxine, biotin, folic acid, vitamin B_{12}, inositol and choline chloride, and halibut oil with added vitamins E and K was given weekly. Amino-acid supplements were added at the expense of sucrose.

When the diet contained 9 per cent. casein, but not with 18 per cent., 1·5 or 3·0 per cent. leucine retarded growth. DL-Leucine was less effective than L-leucine. The effect was decreased by simultaneous addition of 0·5 per cent. DL-*iso*leucine, but not by tryptophan, threonine, valine or a mixture of these 3 with histidine, lysine and phenylalanine. The effect of 1·0 per cent. L-leucine was completely overcome by 0·5 per cent. DL-*iso*leucine, but with more leucine, *iso*leucine was never completely effective, and 0·2 per cent. was as good as 0·8 per cent. With 18 per cent. bloodmeal, which is deficient in *iso*leucine, 2·0 per cent. L-leucine depressed growth except when 2·0 per cent. DL-*iso*leucine was also added.

It is suggested that in the rat, excess leucine is an antimetabolite for *iso*leucine and increases the requirement of the latter.—D. Duncan.

703

BENTON, D. A., HARPER, A. E. and ELVEHJEM, C. A. **Effect of isoleucine supplementation on the growth of rats fed zein or corn diets.** *Arch. Biochem. Biophys.,* 1955, **57,** 13–19. [Dept. Biochem., Univ. Wisconsin, Madison.]

The work described in the preceding Abst. was followed by 6 similar experiments with a total of 25 groups of rats. In the first set of 3 experiments,

10 groups were given diets with zein, 2 with 15 and 8 with 24 per cent., and with one of 3 mixtures containing 7, 8 or 9 amino-acids ; 1 group of rats had 20 per cent. casein with a supplement of DL-methionine. In the second set of 3 experiments, 14 groups were given diets containing about 90 per cent. maize, which for some groups had been extracted with alcohol or Skellysolve B, and all received a simpler mixture of amino-acids, usually only L-lysine, DL-tryptophan, DL-threonine and DL-valine. To these diets further additions of *iso*leucine or leucine were made and in 2 the amounts balanced those in the quantities of zein removed by the alcohol. Records were made of weight gains, and the mean values for 6 in each group are used for comparison.

In both sets of experiments *iso*leucine was found to be a limiting amino-acid. In the group getting 24 per cent. zein, phenylalanine also had that effect. It is suggested that the amino-acids in zein were poorly utilised, since, with alcohol-extracted maize, *iso*leucine equivalent to that in the zein which had been removed improved the rate of growth much more than did zein itself. Leucine in corresponding amount did not depress the rate of growth of the rats.—D. Harvey.

SIME, J. T., and JOHNSON, B. C. **Metabolism of methionine-C^{14}H$_3$ in the chick. 2. Distribution of C^{14} in the urinary uric acid molecule.** *J. Biol. Chem.*, 1955, **215**, 41–44. [Div. Animal Nutrit., Dept. Animal Sci., Univ. Illinois, Urbana.]

Three chickens received for the first 5 weeks of life an adequate diet containing, per cent., maize 55·78, soya bean meal (50 per cent. protein) 34, bonemeal 3·0, limestone 1·0, salt 0·5, vitamin A and D oil 0·05, $MnSO_4$ 0·05, alfalfa 1·0, DL-methionine 0·1, Aurofac 1·0, riboflavin concentrate 0·02 and distiller's solubles 4·0, with nicotinic acid 1 g. and choline 24 g. per 100 lb. At 5 weeks of age an operation was performed on each bird which allowed separate collection of urine and faeces for 36 hr. Eight hours after operation each chick received intraperitoneally 42 mg. methionine-$^{14}CH_3$ and urine was then collected for 36 hr. The uric acid was purified and degraded.

The uric acid recovered contained 9·3 per cent. of the ^{14}C activity injected, and of this 55·9 per cent. was in C atom 2 and 36·5 per cent. in C atom 8, and another 6·7 per cent. was in C atoms 4 and 5. It is concluded that the methyl group of methionine serves as a source of " active 1-carbon compound " for uric acid formation.—D. Duncan.

ASCHKENASY, A. Suppression par le surrénalectomie de la protection du foie par la méthionine contre les effets du régime hypoprotidique. [**Suppression by adrenalectomy of the protection of the liver by methionine against the effects of a diet low in protein.**] *C.R. Soc. Biol.*, 1955, **149**, 663–666. [Hôp. Pitié, Paris.]

A methionine supplement prolonged the survival of adrenalectomised rats on a diet containing 2 per cent. protein, but they did not live as long as intact rats on the same diet. In intact rats on the basal 2 per cent. casein diet the liver weight decreased less than the bodyweight in 35 days, but with methionine the liver was significantly heavier both absolutely and relatively. After adrenalectomy the liver weight was absolutely and relatively less and methionine did not affect it.

Adult and young rats, some of the latter previously kept on a diet deficient in S amino-acids, received intraperitoneal injections of CCl_4. Glutathione in the livers was increased 24 hr. after the injections, particularly in the young rats receiving an adequate diet. Liver extracts from control or treated rats when incubated with cysteine or glutathione lost sulphydryl groups, which were further decreased by chloral hydrate. No direct evidence for the detoxication of CCl_4 by glutathione *in vivo* was obtained.—A. Hepburn.

710

JORDE, W. O. Untersuchungen über den Kreatinstoffwechsel. [**Studies on creatine metabolism.**] *Ztschr. ges. exp. Med.*, 1955, **126**, 145–202. [1. Med. Klin., Univ. Munich.]

Rabbits received a diet of roots, oats, wheat, bread and water. After a week some served as controls, others received a single intramuscular injection of 4 or 7 mg. allyl formate per 100 g. bodyweight, or 3 daily injections of 0·05 or 0·07 ml. CCl_4 per kg. bodyweight. Subgroups of those given allyl formate or CCl_4 received also, beginning 2 days before the toxin, daily injections of 1·5 ml. per kg. bodyweight of 2·5 per cent. solution of creatine or choline. Rabbits given the largest doses of toxin died in 3 or 4 days, the rest were killed after 7 or 21 days. Creatine, creatinine and glycogen were estimated in skeletal muscle, liver and kidney.

The rabbits given the smaller doses of toxin showed histologically only slight liver damage, but in those which died damage was severe. In the first week the creatine contents of liver and kidney fell significantly; that of muscle rose after CCl_4, but not after allyl formate. After 3 weeks allyl formate produced an increase in muscle creatine, by which time rabbits given CCl_4 had normal muscle creatine and rising levels in liver and kidney. Choline was without effect, except that after 3 weeks rabbits given allyl formate and choline had normal muscle creatine. Creatine reduced the creatine content of all 3 tissues after 3 weeks in rabbits given allyl formate, after 1 week in those given CCl_4. It is concluded that experimental liver damage reduces creatine formation in the liver, partly compensated by increased formation in extrahepatic tissues.

Glycogen formation in the muscle was reduced at first, and the glycogen contents of liver and kidney were briefly increased. There was no relation between glycogen and creatine contents of muscle, and creatine and choline injections were without effect.

The effects of injections of 1 g. creatine alone or with vitamin C or of calcium creatine phosphate were studied in 9 normal human subjects and 15 patients with epidemic hepatitis. All the subjects had normal serum creatine and creatinine levels, and injected creatine or calcium creatine phosphate was quickly removed from the blood. Elimination of creatine and creatinine in the urine in the first 2 hr. after injection was less in patients with hepatitis than in the normal subjects. In both groups simultaneous injection of 500 mg. vitamin C increased creatine retention. It is concluded that exogenous creatine can be utilised and can be transformed into creatinine both enzymically and non-enzymically. Creatine metabolism depends on the activity of intermediary carbohydrate metabolism and the supply of creatine precursors in the muscle.

Pyroracemic acid in fasting and at rest was not always found in the blood, but at other times healthy subjects had more than 1·06 mg. per cent. The ratio of pyroracemic to lactic acid in the blood was not constant. The injection of creatine increased blood pyroracemic acid, but not lactic acid. It was concluded that intravenous creatine affected anaerobic carbohydrate metabolism in the tissues.

Parenteral creatine improved Quick's prothrombin time both in the rabbits with experimental liver damage and in the patients with hepatitis.

SPISNI, D. and CAPPA, V. Alimentazione e contenuto di composti indossilici nell'urina di bovini. [**Diet and the amount of indoxyl compounds in the urine of cattle.**] Presenza di indolo nel contenuto del rumine di bovini. [**Presence of indole in the rumen contents of cattle.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 1417–1418; 1418–1419. [Ist. Anat. Fisiol., Fac. Agrar., Univ. Cattolica del Sacro Cuore, Milan-Piacenza.]

Indoxyl substances were estimated in the urine of 78 cattle of different breed, age and origin, some of them pregnant, fed on different hay crops. When the proportion of grasses in the hay was high, the amount of indoxyl substances in the urine was relatively low, and it increased when the proportion of leguminous plants was high. The amount excreted ranged from 0·01 to 0·3 g. per 100 ml. urine.

Indole was always present in rumen contents of 15 cattle just after slaughter; the amount ranged from 0·09 to 3 mg. per litre.—E. M. Hume.

SAHASRABUDHE, M. R. **Digestibility and absorption of hydrogenated blended fats.** *J. Sci. Indust. Res.*, 1954, **13B,** 131–133. [Central Food Technol. Res. Inst., Mysore.]

The fats used were vanaspati, m.p. 37° C., and vanaspati blended with 10, 15 and 25 per cent. of hydrogenated fats of m.p. 41°, 45° and 51° C. Test meals of 3/4 oz. fat. and 1½ oz. bread were given to 6 young girls who had not eaten for 13 hr. Chylomicron counts were made after 1 hr. and then every ½ hr. for 10 hr. Digestibility studies were made on the same subjects; faecal excretion was measured during the last 4 days of 9 days when 20 g. fat was given daily.

Though no significant difference in digestibility was found, chylomicron counts after vanaspati fell to about fasting level in 7 hr., but with the blends the interval was 8 to 10 hr.—G. A. Garton.

720

ROSS, C. A. C. **Fat absorption studies in the diagnosis and treatment of pancreatic fibrosis.** *Arch. Dis. Childhood*, 1955, **30,** 316–321. [Dept. Paediat. Child Health, Univ. Birmingham.]

The subjects were 22 children aged 2 weeks to 5 years, with pancreatic fibrosis, and 18 children under 5 years, with coeliac disease. Estimation of lipase and trypsin in duodenal juice of 17 children with pancreatic fibrosis showed absence of trypsin in all but 2. At a subsequent estimation these 2 also showed no trypsin. Small amounts of lipase were found in 7. In children with coeliac disease, lipase and trypsin values were within the normal range. Fat absorption was studied in 14 children with pancreatic fibrosis. In the 8 children over 1 year of age absorption was less than 60 per cent., in 3 children under 1 year it was less than 60 and in the other 3 under 1 year 72, 80 and 81. Sixteen of the children with coeliac disease absorbed between 70 and 90 per cent. of fat, the other 2 between 50 and 60 per cent. After treatment of coeliac disease with a diet free from wheat gluten, all absorbed over 90 per cent. of fat. Treatment of 11 children with pancreatic fibrosis with pancreatin increased fat absorption from an average of 50 per cent. to 72·8 per cent. The maximum chylomicron increase after a standard fat meal was under 50 in 21 children with pancreatic fibrosis and under 25 in 18. In 18 children with coeliac disease only 3 had a maximum increment below 50. Four of them had increments of over 150. After diet treatment 10 had a maximum increment of over 150. In 4 subjects with pancreatic fibrosis the average maximum increment was increased from 7 to 151 by pancreatin treatment.—F. C. Aitken.

BLOMSTRAND, R. **A study on the intestinal absorption of fat in normal adults and in non-tropical sprue with carbon-labelled oleic acid and palmitic acid.** *Acta med. scand.*, 1955, **152,** 129–138. [Dept. Med., Univ. Lund.]

The faecal lipids of 2 normal subjects and of one with non-tropical sprue were analysed before, after and during 3 days on a diet containing oleic and palmitic acid labelled with ^{13}C; for 3 days before and 3 days afterwards the diet contained 40 g. olive oil daily as almost the only fat.

Both normal subjects absorbed 99·4 per cent. of the labelled acids; about 1 g. faecal fatty acids daily was of endogenous origin. In the patient with sprue, 76·5 per cent. of the labelled acids was absorbed and about 3 g. faecal fatty acids daily was of dietary origin; when the faecal fatty acids were separated into saturated and unsaturated acids and the isotope concentration of each group was estimated, it appeared that some unabsorbed oleic acid had been hydrogenated.—G. A. Garton.

MANN, G. V., TEEL, K., HAYES, O., MCNALLY, A. and BRUNO, D. **Exercise in the disposition of dietary calories: regulation of serum lipoprotein and cholesterol levels in human subjects.** *New Engl. J. Med.*, 1955, **253,** 349–355. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Four healthy young male students were subjects of a 10-week experiment. In the first week, the control period, food was allowed to appetite and the students followed their usual activities and maintained their bodyweight at a nearly constant level. For the 4 subjects average daily intake of energy ranged from 2788 to 3093 Cal. and of fat from 155 to 175 g. In the second period, lasting 4 weeks, energy intake was doubled while fat intake remained the same, and the subjects were required to do strenuous exercise to maintain bodyweight within 5 lb. of the mean value for the control period. In the next 3 weeks high energy intake was maintained and energy expenditure was reduced to that of the control period, so that subjects gained weight. In the final 2 weeks the subjects were restricted in energy intake and exercised to lose fat deposited in the previous period. During the experiment body volume was estimated and body composition computed ; blood samples were analysed weekly for lipoproteins and lipids ; urine samples were collected weekly for measurement of excretion of creatinine. Three subjects completed the experiment.

Doubling the energy intake did not raise the levels of serum lipoproteins and cholesterol so long as surplus energy was expended in heat and muscular work. Deposition of adipose tissue caused the serum lipids to increase in 2 of 3 subjects.

The findings are discussed in relation to atherosclerosis in American men.—F. C. Aitken.

724

BEVERIDGE, J. M. R., CONNELL, W. F., MAYER, G. A., FIRSTBROOK, J. B. and DEWOLFE, M. S. **The effects of certain vegetable and animal fats on the plasma lipids of humans.** *J. Nutrition*, 1955, **56,** 311–320. [Dept. Biochem., Fac. Med., Queen's Univ., Kingston, Ont.]

Free and total cholesterol and phospholipins were estimated in the plasma of 5 apparently healthy men aged from 33 to 41 years, during a period when they consumed alternately their customary diets and diets of known composition. The latter included differing proportions of skimmed milk powder, maize oil or margarine or butter and dextrinmaltose, supplemented as required with small amounts of cholesterol.

When the subjects ate diets which included vegetable fat as 28·4 or 58·5 per cent. of the total energy, with or without supplementary cholesterol, plasma lipid values were lower than when a mixed diet was eaten. When butter supplied 58·5 per cent. of the energy intake, plasma lipid values rose temporarily, then fell.—G. A. Garton.

725

HATCH, F. T., ABELL, L. L. and KENDALL, F. E. **Effects of restriction of dietary fat and cholesterol upon serum lipids and lipoproteins in patients with hypertension.** *Amer. J. Med.*, 1955, **19,** 48–60. [Res. Serv., First (Columbia Univ.) Div., Goldwater Mem. Hosp., New York.]

Forty-four patients with severe essential hypertension were given a low-salt diet of normal fat content for 4 to 18 weeks, followed by the Kempner rice diet for 4 to 20 weeks. Ten of the patients then had the rice diet supplemented by protein and fat in the form of low-Na milk and a protein-carbohydrate powder ; 10 patients received a special low-Na diet of greater palatability than the rice diet and 6 additional patients were studied on this diet without a preliminary period on the rice diet. Serum was analysed for free and total cholesterol, lipid P and neutral fat at intervals throughout the study. Fasting blood samples were used for estimation of the Sf 12–20 and Sf 20–100 lipoprotein fractions by means of the ultracentrifuge.

Restriction of dietary fat and elimination of cholesterol did not reduce the serum lipid or lipoprotein level below the normal range in any patient. Drastic restriction of fat and cholesterol produced variable effects on the serum lipid patterns of the patients. Serum cholesterol esters usually declined when the fat intake was below 40 g. daily, but free cholesterol and lipid P showed no consistent change ; one-fifth of the patients on such restricted diet exhibited lipaemia, due chiefly to serum neutral fat. Dietary restriction did not significantly alter the concentration of the Sf 12–20 lipoprotein fraction, but produced substantial increases in the Sf 20–100 fraction. Restriction of fat rather than restriction of cholesterol was responsible for the changes in serum cholesterol and other lipids.—G. F. Garton.

HAMMOND, E. G. and LUNDBERG, W. O. **The effect of low-fat diet and atherosclerosis on the polyunsaturated fatty acids of human blood plasma.** *Arch. Biochem. Biophys.*, 1955, **57,**

517–519. [Dept. Agric. Biochem., Univ. Minnesota, St. Paul.]

The total fatty acid content of plasma from atherosclerotic patients, from Guatemalan natives who eat a low-fat diet and from a blood bank was estimated ; the polyunsaturated acids containing 2, 3, 4, 5 and 6 double bonds were estimated by a micro alkali-isomerisation technique.

In spite of the low intake of fat the Guatemalan samples had a greater amount of trienoic acids, expressed as a percentage of total fatty acids, than the blood bank plasma, and on the same basis the amounts of penta- and hexaenoic acids were probably also greater. On the basis of mg. acid per unit volume of plasma only the trienoic and hexaenoic acid contents of the Guatemalan were higher than in blood bank plasma.

In the plasma from atherosclerotic subjects the level of total fatty acids was considerably higher than that in blood bank plasma. Expressed as a percentage of total fatty acids, the atherosclerotic subjects had lower plasma levels of dienoic and tetraenoic acids and a higher level of trienoic acids than blood bank plasma. Expressed as mg. fatty acid per unit volume of plasma the amounts of dienoic and tetraenoic acids were not different from those in bank plasma, but the amounts of trienoic and hexaenoic and probably of pentaenoic acids were higher in the plasma of the atherosclerotic subjects.

It is suggested that a relation may exist between atherosclerosis and changes in the plasma content of polyunsaturated fatty acids.—G. A. Garton.

727

KEYS, A., ANDERSON, J. T., FIDANZA, F., KEYS, M. H. and SWAHN, B. **Effects of diet on blood lipids in man: particularly cholesterol and lipoproteins.** *Clin. Chem.*, 1955, **1**, 34–52. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

Serum from healthy men was analysed for total cholesterol and for lipoproteins; α- and β-lipoprotein fractions were further analysed for lipids and cholesterol. The groups of men included subjects in different occupations in the United States, Italy, Sweden, Spain, South Africa and England. The effects of different diets were studied in schizophrenic patients who were metabolically " normal ".

A direct relation existed between the proportion of fat in the diet and the concentrations of serum total cholesterol and of serum β-lipoproteins ; the effect of diet tended to be greater in middle-aged than in younger men. The mean level of serum cholesterol was 25 to 50 per cent. higher in men in whose diet 40 per cent. of the energy value was supplied by fat than in men on diets in which fat contributed 20 per cent. or less of the total energy.

Changing the proportion of fat in the diet led to changes in the serum cholesterol values. Little is known, as yet, of the mechanism by which food fat influences the composition of blood lipids.

SCHETTLER, G. and JOBST, H. Die Bedeutung alimentärer Fettbelastungen für die Diagnose der Arteriosklerose. [**Significance of alimentary fat tests for the diagnosis of arteriosclerosis.**] *Deutsch. med. Wochenschr.*, 1955, **80**, 1077–1081. [Med. Klin., Univ. Marburg a.d. Lahn.] English and Spanish summaries.

Serum lipids and chylomicron curves were followed before and for 5 hr. after a meal containing 0·5 g. butter per kg. bodyweight in 10 young normal persons aged from 22 to 39 years, in 10 older normal persons aged from 42 to 67 years and in 10 patients aged from 41 to 71 years with arteriosclerosis and coronary thrombosis.

There was no significant difference between the fasting values for number of chylomicrons, total number and percentage of large chylomicrons, turbidity, phospholipins, free cholesterol and cholesterol esters for the younger and the older normal groups ; the neutral fat (total esters of the fatty acids) was higher in the older group, but the result was doubtfully significant. After the fat meal the values for total chylomicrons, large chlyomicrons and absolute turbidity as well as that for neutral fat were significantly higher in the older group than in the younger.

A comparison of the values in the arteriosclerotic group with those in the young controls showed that the fasting values for turbidity, neutral fat and cholesterol and cholesterol esters were significantly raised in the arteriosclerotic group and that after the fat meal the values for total chylomicrons, large chylomicrons, absolute turbidity and especially neutral fat were also significantly raised in this group. However, in comparison with the older normals who showed the same trend in their blood findings as the arteriosclerotics, there was a significantly greater rise in the arteriosclerotics in both the fasting value and value after the fat meal for neutral fat and in the fasting value for the percentage of large chylomicrons and for free cholesterol. The fat meal did not alter the blood level of cholesterol, cholesterol esters or phospholipins in any of the groups. The discrepancy between turbidity value and neutral fat values was thought to result from the presence of neutral fat particles too small to be resolved by the dark ground microscope in arteriosclerotic serum. It is suggested that estimations of neutral fat combined with chylomicron curves and turbidity estimations may be of value in the diagnosis of arteriosclerosis.—L. Wills.

MOSER, H. W. and EMERSON, K. (Jr.) **Estimation of the phospholipid phosphorus turnover time in man: studies in normal individuals, in patients with the nephrotic syndrome and in other types of hyperlipemia.** *J. Clin. Invest.*, 1955, **34,** 1286–1296. [Dept. Med., Harvard Med. Sch., Boston, Mass.]

The specific activity of plasma lipoid P and urine phosphate was studied in 6 normal subjects and in 8 hyperlipaemic patients after intravenous injection of 1·0 to 2·2 μC. $^{32}PO_4$ per kg. bodyweight.

The turnover time of phospholipoid P contained in plasma plus liver was calculated as 60 to 95 hr. in the normal subjects. In the hyperlipaemic subjects suffering from nephrosis and in 1 with untreated hypothyroidism the specific activity of plasma lipoid P relative to that of urine phosphate increased more slowly than in normal subjects; in a hyperlipaemic patient with biliary cirrhosis it increased at almost the normal rate. The values for a patient with familial hypercholesterolaemia and *xanthoma tendinosum* were intermediate. It is suggested that in nephrotic patients there was a delay in the attainment of isotopic equilibrium between liver and plasma phospholipins.

731

SIMMONDS, W. J. **The intestinal absorption of fat, fatty acid and fat soluble dye into thoracic duct lymph in unanaesthetized rats.** *Austral. J. Exp. Biol. Med. Sci.*, 1955, **33,** 25–32. [Kanematsu Mem. Inst. Pathol., Sydney Hosp.]

Unanaesthetised fasting rats with cannulae in their thoracic lymph ducts were given 0·5 ml. olive oil or oleic acid containing dissolved Sudan IV. Lymph flow was measured half-hourly and fat and dye concentrations were estimated from 0 to 1, 1 to 3, 3 to 6 and 6 to 10 hr. later.

Dye recovered from the lymph was usually 15 to 20 per cent., fat from 70 to 80 per cent. of that given. The recovery pattern was not the same for both lipids; dye and fat recovery rose more rapidly to a higher maximum value and fell more rapidly after olive oil than after oleic acid.

The results are discussed in relation to Frazer's hypothesis of fat absorption (Abst. 582, Vol. 25).

G. A. Garton.

732

SIMMONDS, W. J. **Some observations on the increase in thoracic duct lymph flow during intestinal absorption of fat in unanaesthetized rats.** *Austral. J. Exp. Biol. Med. Sci.*, 1955, **33,** 305–313. [Kanematsu Mem. Inst. Pathol., Sydney Hosp.]

In experiments similar to those described in the preceeding Abst., the rate of flow and composition of thoracic duct lymph were studied after 1 to 4 g. powdered skimmed milk, 1 g. powdered full cream milk or 0·5 ml. olive oil, oleic acid or tributyrin was given to unanaesthetised rats.

No significant change in the composition or rate of flow of lymph was found after skimmed milk, but lipid, alone or in mixed food, caused a considerable increase in lymph flow. Since lymph flow increased concurrently with increasing lymph fat recoveries after full cream milk, olive oil or oleic acid, it is suggested that absorption rather than digestion determines the rate of flow. Tributyrin did not appear in the lymph, but its administration was followed by an increase in lymph flow and a decline in the amount of lymph protein.

KADYKOV, B. I. and SHASTIN, R. N. O printzipe vychisleniya koefitzienta usvoeniya zhira. [**Principles involved in calculating the coefficient of assimilation of fat.**] *Vop. Pitan.*, 1955, **14,** No. 4, 14–17. [Sanit.-Gig. Inst., Leningrad.]

In rats given diets containing different amounts of fat or none there was a fairly constant amount of faecal fat, about 15 mg. daily, which had its origin in the intestinal wall and was excreted even on the fat-free diet. This must be taken into account in calculating the coefficient of absorption of dietary fat.—D. W. Taylor.

734

SCHRADE, W., BIEGLER, R. and BECKER, G. Über die Beteiligung der Lunge am Fettstoffwechsel. [**Role of the lung in fat metabolism.**] *Ztschr. ges. exp. Med.*, 1955, **126,** 125–140. [1. Med. Klin., Frankfurt a.M.]

Rats received a meal of 1 to 3 ml. olive oil. At different intervals afterwards they were anaesthetised and perfused through the right ventricle with physiological saline until the lungs were completely free of blood. Lung tissue was then analysed for fat. Control rats not given oil had lungs with a mean total fat content of 20·5 per cent. on a dry matter basis. In 26 rats killed 8 hr. after the fat meal the lung fat was 42·7 per cent. After longer intervals it sank again, approaching the initial value at 24 hr.

In a second series of 10 fasted rats and 10 given oil as before, the fat contents of liver, kidneys and

spleen as well as lung were estimated 8 hr. after the meal. The fat content of the lung in the control and fat-fed groups was 18·8 and 44·8 per cent. of dry matter, an absolute difference of 53·7 mg. In liver the fat contents were 18·6 and 24·2 per cent., absolute difference 64·2 mg. In kidney and spleen there was no significant difference. The iodine value, the phosphatide fraction and especially the non-phosphatide fraction of lung fat were all increased after the fat meal.

In rats given 3 fat meals 4 hr. apart and killed 4 hr. after the last, the lung fat was only 21·17 mg. more than in fasted rats, whereas the liver fat had increased by 104·7 mg.

From the qualitative changes in lung fat it is concluded that the lungs are actively concerned in fat metabolism.—D. Duncan.

735

VARTIAINEN, I. and TELKKÄ, A. **Effect of high fat diet on the pancreatic islets of rat.** *Ann. Med. int. Fenn.*, 1955, **44,** 79–88. [2 Med. Clin., Univ. Helsinki.]

Two groups of rats were maintained for a year on a purified diet containing 15 per cent. casein and 5 or 80 per cent. fat with vitamin supplements. There was no significant difference between the groups in weight, glucose tolerance, water intake or size of thyroid. With the high-fat diet the weight of the liver was lower and the weight of the adrenal was higher, with hypertrophy of the adrenal cortex; the islets of Langerhans made up only 0·9 per cent. of the pancreatic tissue, but with the low-fat diet the islet tissue constituted 2·6 per cent. No change in glucose tolerance occurred until a considerable part of the pancreas had been removed.—A. M. Copping.

736

NIEMAN, C. **Influence of dietary fat on incidence of alloxan diabetes in growing rats.** *Amer. J. Physiol.*, 1955, **181,** 183–186. [Netherlands Inst. Nutrit., Amsterdam.]

Groups of weanling rats were fed on diets containing 10 or 20 per cent. of butterfat or groundnut oil and were made diabetic by injection of alloxan. As judged by growth rate, growth per g. food eaten, incidence of diabetes and mortality rate, butterfat afforded more protection from the effects of alloxan than did groundnut oil; it is suggested that its protective value may be associated with the content of short-chain fatty acids, greater saturation of the fat as a whole, or both.—G. A. Garton.

FAVARGER, P. and GERLACH, J. Recherches sur la synthèse des graisses à partir d'acétate ou de glucose. 1. Vitesse d'incorporation de l'acétate dans les acides gras de la souris amaigrie. [**Synthesis of fats from acetate or glucose. 1. Rate of incorporation of acetate into the fatty acids of the starved mouse.**] 2. Les rôles respectifs du foie, du tissue adipeux et de certains autres tissus dans la lipogenèse chez la souris. [**2. Respective roles of liver, adipose tissue and certain other tissues in lipogenesis in the mouse.**] *Helv. physiol. pharm. Acta*, 1955, **13,** 91–95; 96–105. [Inst. Chim. Physiol., Univ. Geneva.]

1. Starving mice were given an intraperitoneal or subcutaneous injection of 2·5 or 5·0 μC. acetate-1-^{14}C and were killed 3, 12 or 30 min. later. Fatty acids were isolated from organs and from the carcases and assayed for ^{14}C activity. The speed of incorporation of acetate into fatty acids in the different tissues examined was too great to allow comparison of rates of lipogenesis.

2. Acetate-1-^{14}C or glucose uniformly labelled with ^{14}C was injected into the caudal vein of starving mice. The animals were killed after 3, 12 or 30 min. and the fatty acids of tissues were assayed for ^{14}C activity. The specific activity of the fatty acids isolated from intercapsular fatty tissue, lung and intestine was greater than that of liver fatty acids, and it is concluded that the role of the liver in lipogenesis has been overestimated in the past.—G. A. Garton.

BATES, M. W., ZOMZELY, C. and MAYER, J. **Fat metabolism in three forms of experimental obesity. 4. 'Instantaneous' rates of lipogenesis *in vivo*.** *Amer. J. Physiol.*, 1955, **181,** 187–190. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

See also Abst. 5292, Vol. 25.

Groups of fed and fasting mice with hereditary obesity and diabetes or rendered obese by injection of goldthioglucose and of rats rendered obese by hypothalamic section were given intraperitoneal injections of ^{14}C-carboxyl-labelled acetate. The animals were killed 30 min. later and the extent of incorporation of ^{14}C into liver and carcase lipids was studied.

Between 60 and 70 per cent. of the incorporated ^{14}C was found in adipose tissue in control mice and 80 per cent. in control rats. In the fasting state the incorporation of ^{14}C-acetate was depressed in liver more than in peripheral tissue, indicating that fat formation in the liver is more dependent on feeding than it is in other parts of the body.

When they were fed to appetite the 3 types of obese animals, particularly the hypothalamic rats, deposited more liver and carcase fat than did their controls. Fasting obese-diabetic mice synthesised more fat than did their controls, but the

goldthioglucose mice and the hypothalamic rats did not.

The differences in fat synthesis are discussed in relation to the etiology of obesity.—G. A. Garton.

739

YOUNG, D. R. and COOK, S. F. **Body lipids in small mammals following prolonged exposures to high and low temperatures.** *Amer. J. Physiol.*, 1955, **181,** 72–74. [Dept. Physiol., Univ. California, Berkeley.]

The total lipid content of 3 groups of young male mice was estimated after they had been kept for 30 to 36 days at 4°, 24° (control) and 35° C., respectively; all received the same diet to appetite. The mice at 4° C. ate more than the controls, but deposited less body fat. The mice at 35° C. ate less than the controls but deposited similar amounts of body fat.

Similar results were obtained with groups of male and female rats kept under the same conditions as the mice for 150 and 130 days, respectively. The lipids were extracted separately from skin and carcase. The melting-point of carcase lipids showed a tendency to rise with environmental temperature but skin lipids showed about the same melting-point at all environmental temperatures.

WILHELMJ, C. M., GUNDERSON, D. E., SHUPUT, D. and MCCARTHY, H. H. (with GREEN, G. B.) **The effect of diet on the blood pressure and heart rate of normal dogs. Animal fat.** *Amer. J. Digest. Dis.*, 1955, **22,** 219–227. [Dept. Physiol., Sch. Med., Creighton Univ., Omaha, Nebr.]

Dogs, 3 male and 3 female, were used. During 2 years they were given high-fat diets for 13 to 42 days on 2 to 6 occasions, each time after a prolonged fast. In the high-fat diets 50 per cent. or more of the energy was from beef fat or butter. Throughout the experiment blood pressure was estimated on 6 days weekly; total white blood cell and eosinophil counts were recorded daily. Liver function tests with bromosulphthalein were made frequently.

Four of the dogs showed gradual physiological changes. The fall in blood pressure normally associated with fasting was replaced in the fasting period either by failure of the blood pressure to fall or by a progressive increase. Blood pressure while the animals were on the high-fat diet was usually normal or low, though occasionally high. After several periods of high-fat diet the blood pressure of animals given a balanced high-energy diet was abnormally high; there was also pronounced and persistent eosinopenia. Three of the dogs were made to work on a treadmill or exposed to cold after several periods on the high-fat diet, but no exaggerated blood pressure change resulted.—G. A. Garton.

741

BEST, C. H., HARTROFT, W. S., LUCAS, C. C. and RIDOUT, J. H. **Effects of dietary protein, lipotropic factors, and re-alimentation on total hepatic lipids and their distribution.** *Brit. Med. J.*, 1955, i, 1439–1444. [Banting and Best Dept. Med. Res., Univ. Toronto.]

In 5 experiments on 300 rats, diets were given usually to appetite for 3 weeks; the rats were then killed and the livers were removed for histological examination and analysed for total lipids. In the first experiment 4 groups each of 6 rats were given diets containing 3, 6, 9 or 18 per cent. protein as casein, the total methionine being kept constant at 0·54 per cent.; in the second experiment the total methionine was again kept constant at 0·54 per cent. for 5 groups of 8 rats which received a diet with either fibrin or soya bean protein or mixtures of these. In the third experiment groups of 10 rats were given 3 per cent. casein without or with 0·45 per cent. DL-methionine, or a high-protein diet containing less than half as much methionine as in 18 per cent. casein; these diets were given alone or supplemented with 0·5 per cent. choline chloride. In the fourth experiment the effect was studied of a diet containing only 2 per cent. soya bean protein plus 1 per cent. groundnut protein, given for 85 days. In the fifth experiment 40 rats were given the 3 per cent. casein diet supplemented with methionine to make it equivalent in that respect to the 18 per cent. casein diet, both diets containing 0·5 per cent. choline chloride; pairs of rats were killed after 2, 4, 8 and 16 days and the remaining 32 were transferred to the 18 per cent. casein diet; groups of 8 rats were then killed after 3, 7, 14 and 21 days. Another 25 rats were given "master fox chow"; during the first 16 days they were pair-fed with those on the low-protein diet; 5 rats were then killed, the remainder were allowed the chow to appetite and groups of 5 were killed after 3, 7, 14 and 21 days.

Inadequate supply of protein resulted in the rapid appearance of stainable fat in periportal regions of the liver, without the massive accumulation of hepatic lipids seen in choline deficiency; in rats on diets containing a moderate amount of fat and 9 per cent. or less of protein supplementary choline did not completely prevent the accumulation of fat in periportal regions of the liver. The transference of rats from the low- to the adequate-protein diet produced a dramatic appearance of a transient fatty liver, the fat appearing in periportal regions only; during the 3 weeks on the adequate protein intake the hepatic lipids returned to normal. The rats on the commercial chow diet did not develop fatty livers.—G. F. Garton.

742

WILGRAM, G. F. and HARTROFT, W. S. **Pathogenesis of fatty and sclerotic lesions in the cardiovascular system of choline-deficient rats.** *Brit. J. Exp. Pathol.*, 1955, **36,** 298–305. [Banting and Best Dept. Med. Res., Univ. Toronto.]

For details of the diets and experimental procedures see Absts. 3240, Vol. 23 ; 822, 839, Vol. 25. The choline-deficient rats had coronary arterial lipoidosis, gross aortic sclerosis and myocardial necrosis in both acute and chronic form. When the diet was supplemented with choline no comparable lesion was seen. The initiation of the cardiovascular lesions was accompanied by deposition of stainable fat, which appeared within a few days in heart muscle cells that subsequently became necrotic. Intimal fat in coronary arteries preceded endothelial hypoplasia and narrowing of the lumen. Fat deposits in the aorta were followed by the development of intimal plaques and calcification and necrosis of the underlying media. The walls of coronary arteries, aortas and cardiac muscle fibres showed a positive haemosiderin reaction. When cholesterol was added to the choline-deficient diet the pathological effects of choline deficiency were aggravated, though serum cholesterol values were not altered.—G. A. Garton.

743

HARTROFT, W. S. **Effects of various types of lipids in experimental hypolipotropic diets.** *Federation Proc.*, 1955, **14,** 655–660. [Dept. Pathol., Med. Sch., Washington Univ., St. Louis, Mo.]

744

BENTON, D. A., HARPER, A. E., WINJE, M. E. and ELVEHJEM, C. A. **Compounds other than threonine that affect fat deposition in the livers of rats fed low protein diets.** *J. Biol. Chem.*, 1955, **214,** 677–684. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

For earlier related papers see Absts. 3211, 3213, Vol. 23 ; 710, Vol. 24 ; 819, Vol. 25. Groups of male weanling rats were fed on a low-protein diet containing choline and methionine, to which were added single amino-acids and other substances containing N.

Leucine, glutamic acid, aspartic acid and benzoic acid prevented excess deposition of fat in liver. Equimolar amounts of glycine, serine and glutamic acid caused reductions of the same order in the amount of liver fat which accumulated, though an equivalent supplement of choline was more effective. Ammonium citrate, ammonium acetate and urea did not reduce liver fat.

G. A. Garton.

745

WEITZEL, G., SCHÖN, H., GEY, F. and KALBE, H. Stoffwechselversuche mit Fettsäuren mittlerer Kettenlänge. 1. Fettsäuren mittlerer Kettenlänge im Hautstoffwechsel. [**Metabolism experiments with fatty acids of intermediate chain length. 1. Fatty acids of intermediate chain length in skin metabolism.**]

GEY, F., SCHÖN, H., KALBE, H. and WEITZEL, G. 2. Mittlere Fettsäuren im Hautstoffwechsel bei cholinarmer Kost. [**2. Intermediate fatty acids in skin metabolism on a low-choline diet.**]

SCHÖN, H., GEY, F., STRECKER, F. J. and WEITZEL, G. 3. Futterungsversuche mit Laurinsäureestern. [**3. Feeding experiments with lauric acid esters.**] *Hoppe-Seyler's Ztschr.*, 1955, **301,** 118–131 ; 132–142 ; 143–155. [Med. Forschungsanst., Max-Planck-Gesellsch., Göttingen.]

1. See Abst. 3836, Vol. 25.

2. The methods were similar to those described in part 1. The low-choline basal diet contained, per cent., ethanol-extracted casein 8, gelatine 12, cellulose powder 5, wheat germ oil 1, cod liver oil 1, vitamin mixture (containing vitamin B_1, riboflavin, pyridoxine, Ca pantothenate and nicotinic acid) 1 and salt mixture 4, with from 10 to 40 per cent. of the glycerides or fat to be studied, and sucrose to 100.

When the mixture of C_8, C_{10} and C_{12} triglycerides formed 37 or 40 per cent. of the diet the rats lost weight, but at no concentration did it produce fatty livers, though lard or olive oil did. The amount and composition of fatty acids in the skin and subcutaneous tissue were similar to those found when the diet contained choline. It was concluded that choline has no lipotropic effect on the fat metabolism of the skin.

3. The methods and diets were those described above, but the stock or choline-free experimental diets included 10 or 35 per cent. lauric acid ethyl ester, or 10 per cent. of this ester plus 30 per cent. trilaurin, or 35 per cent. lauric acid methyl ester.

With small amounts of the triglyceride or the esters the total fatty acids of skin and subcutaneous tissue, especially the latter, contained up to 7 per cent. lauric acid. The choline content of the diet did not affect this deposition. With large amounts of esters, 35 to 40 per cent. of the diet, and the low-choline diet, only 5 out of 53 rats died, but these 5 and many of the survivors were found to have damaged hearts.—D. Duncan.

746

LOSSOW, W. J. and CHAIKOFF, I. L. **Carbohydrate sparing of fatty acid oxidation. 1. The relation of fatty acid chain length to the degree of sparing. 2. The mechanism by which carbohydrate spares the oxidation of palmitic acid.** *Arch. Biochem. Biophys.*, 1955, **57,** 23–40.

[Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

1. Fasted and carbohydrate-fed rats were injected intravenously with ^{14}C-carboxyl-labelled fatty acids of the even series C_8 to C_{16} and the triglycerides of ^{14}C-carboxyl-labelled palmitic and capric acids. The respired CO_2 was collected for 24 hr. and examined for radio-activity; specific activity : time curves were derived for each animal.

Oxidation of the fatty acids to CO_2 was less in the carbohydrate-fed than in the starving rats and this sparing action was more pronounced with the longer-chain acids. The sparing action lasted several hours, to be followed by a second rise in specific activity of respiratory CO_2.

2. To study further the sparing action of carbohydrate on fatty acid oxidation, palmitic acid-1-^{14}C was injected into fasting and carbohydrate-fed rats which were killed 5 hr. later. Triglycerides were isolated from the liver and carcase lipids and the ^{14}C content of the carboxyl carbon atom and the decarboxylated portions of the 16- and 18-carbon atom fatty acids was estimated; the liver and carcase, after extraction of lipids, were extracted with 10 per cent. trichloroacetic acid and the extracts were combined with aqueous extracts obtained in the course of extraction of the lipids. This combination of aqueous solutions was examined for ^{14}C. It was concluded that carbohydrate spared oxidation of palmitic acid by restricting breakdown of the molecule, rather than by promotion of synthesis from acetyl-S-coenzyme A, the known breakdown product of long-chain fatty acids.—G. A. Garton.

747

PRIVETT, O. S., PUSCH, F. J. and HOLMAN, R. T. **Polyethenoid fatty acid metabolism. 8. Non-potency of *cis*-9, *trans*-12-linoleate as essential fatty acid.** *Arch. Biochem. Biophys.*, 1955, **57**, 156–162. [Hormel Inst., Univ. Minnesota, Austin.]

For part 7 see Abst. 4820, Vol. 24.

Forty male rats were fed for 10 months from weaning on a fat-free diet, on which they showed the skin signs of essential fatty acid deficiency. They were then divided into 8 groups of 5 and were given the fat-free diet for 1 month, but supplemented with (1) 3 per cent. urea, (2) 0·4 per cent. ethyl linoleate, (3) 4·0 per cent. ethyl linoleate, (4) 0·4 per cent. ethyl *cis*-9, *trans*-12-linoleate and 3·6 per cent. urea, (5) 4·0 per cent. ethyl *cis*-9, *trans*-12-linoleate, (6) 3·6 per cent. ethyl linolenate, (7) 3·6 per cent. ethyl linolenate and 0·4 per cent. ethyl linoleate and (8) 3·6 per cent. ethyl linolenate and 0·4 per cent. ethyl *cis*-9, *trans*-12-linoleate. All the substances added to diets 2 to 8 were in the form of urea-inclusion compounds (see Abst. 2286, Vol. 25). At the end of the experiment the rats were killed and total carcase fat was analysed for polyunsaturated fatty acids by the alkali-isomerisation technique; representative fat samples were examined in an infrared spectrophotometer for the presence of *trans*-acids.

Ethyl *cis*-9, *trans*-12-linoleate could not replace essential fatty acids, as judged by its effect on water intake, growth or skin condition. The *cis-trans* isomer was unable to promote the utilisation of linolenate, as judged by skin signs and water intake, but rats given linolenate plus the *cis-trans* isomer of linoleate gained more weight than those given either supplement singly. All the rats given linolenate produced body fat of high pentaenoic and hexaenoic fatty acid and low tetraenoic fatty acid content. *Trans* double bonds derived from the *cis-trans* linoleate were found in body fat. Linoleate must therefore be of the *cis-cis* configuration, as it occurs naturally, to possess complete biological activity as an "essential" fatty acid.—G. A. Garton.

PEIFER, J. J. and HOLMAN, R. T. **Essential fatty acids, diabetes, and cholesterol.** *Arch. Biochem. Biophys.*, 1955, **57**, 520–521. [Hormel Inst., Univ. Minnesota, Austin.]

Male weanling rats were given a diet deficient in essential fatty acids (Abst. 2286, Vol. 25) and 4 days later were made diabetic by injection of alloxan. The animals were then divided into 4 groups, one of which continued to receive the deficient diet, while the others received supplements of 1 per cent. maize oil esters, or 1 per cent. cholesterol, or both. To ensure that diabetes was maintained a second injection of alloxan was given a fortnight after the first. After 31 days the change in weight and the condition of the skin were recorded.

The diabetic animals were rapidly depleted of essential fatty acids; the rate of growth and the appearance of the skin at 31 days were similar to those usually found after 3 months of depletion. Cholesterol did not appear to influence the development of essential fatty acid deficiency in diabetic rats.

Deficiency of essential fatty acids in the diabetic rat and deficiency intensified by dietary cholesterol in non-diabetic rats are similar, and it is suggested that atherosclerosis may be a manifestation of deficiency of essential fatty acids or faulty metabolism of these acids.—G. A. Garton.

JOHNSON, R. B. **The effects of the administration of acetic, propionic, and *n*-butyric acids upon the blood glucose and ketone body levels of goats.** *Cornell Vet.*, 1955, **45**, 273–290. [Live

Stock Sanit. Serv. Lab., Univ. Maryland, College Park.]

Acetic, propionic and *n*-butyric acid alone or in combination were given to goats by vein or into the rumen. Acetic and *n*-butyric acid formed ketone bodies, but this action was counteracted by propionic acid. Propionic acid raised blood glucose. The experimental method did not allow fine observations on blood glucose, but it was clear that acetic and *n*-butyric acid did not raise it as much as propionic acid.—T. D. Bell.

WILKINSON, C. F. (Jr.), BOYLE, E., JACKSON, R. S. and BENJAMIN, M. R. **Effect of varying the intake of dietary fat and the ingestion of sitosterol on lipid and lipoprotein fractions of human serum.** *Metabolism*, 1955, **4,** 302–309. [Dept. Med., Post-Grad. Med. Sch., Univ. New York.]

Seven hospital patients were used in this study; 4 had angina pectoris, 2 had *xanthoma tuberosum* and/or *tendinosa* (1 of these also had angina) and the last was a child with nephrosis. Blood lipids were estimated and serum was analysed by the ultracentrifuge at intervals. The patients were successively given 4 different diets; (1) a mixture of foodstuffs yielding less than 0·25 g. fat daily, (2) an isocaloric mixture of the same N content, but containing 49 g. coconut oil daily, (3) the coconut oil diet with 30 to 60 ml. of an emulsion containing $16\frac{2}{3}$ per cent. sitosterols and (4) food of the patient's own choice, with more than 30 ml. daily of the sitosterol emulsion.

The low-fat diet initially depressed serum total cholesterol in all 7 patients; this trend was arrested or reversed during the second week of fat restriction. The serum cholesterol was not affected in 35 weeks by the addition of sitosterols to the high-fat diet or to free-choice diets. Considerable individual variation in lipoprotein values occurred and no single component could be directly compared with total serum cholesterol in all patients, though the beta$_1$(— S 28–44) fraction seemed to follow the cholesterol more than any other lipid component.—G. A. Garton.

752

BARBER, J. M. and GRANT, A. P. **The serum cholesterol and other lipids after administration of sitosterol.** *Brit. Heart. J.*, 1955, **17,** 296–298. [Ards and Bangor Hosps., Belfast.]

Twenty-six human subjects with coronary artery disease all had initial serum cholesterol values of 230 mg. per 100 ml. or more. β-Sitosterol, 9 g. daily, was given in the form of palatable biscuits and weekly or fortnightly estimations of serum total cholesterol, lipoid P, total lipids and neutral fats were made.

The administration of β-sitosterol brought about a fall in serum total cholesterol which was suggestive, but not significant. In a note added after completion of the paper it is stated that a rapid and consistent fall in serum cholesterol occurred in 6 other patients given 18 g. sitosterol daily.

G. A. Garton.

BEST, M. M., DUNCAN, C. H., VAN LOON, E. J. and WATHEN, J. D. **The effects of sitosterol on serum lipids.** *Amer. J. Med.*, 1955, **19,** 61–70. [Dept. Med., Sch. Med., Univ. Louisville, Ky.]

Fourteen subjects, of whom 12 had high serum cholesterol levels, were allowed food to appetite and were given 6 to 8 g. of β-sitosterol by mouth immediately before meals for from 13 to 64 weeks; the usual intake of β-sitosterol was 20 to 25 g. daily. Fasting blood samples were analysed at intervals for total cholesterol, lipid P and total lipid. In 7 subjects the effect of sitosterol on serum lipoproteins, as estimated by ultracentrifuge, was studied.

A sustained fall of serum total cholesterol occurred, with concomitant reduction in serum total lipid, neutral fat and, to a less extent, lipid P. There was a trend towards lower levels of the S_f 3–10, 10–30 and 30–100 fractions of lipoproteins; this effect was less consistent than the effect on serum total cholesterol. It is suggested that sitosterol interferes with cholesterol absorption by competing with it for esterification in transport mechanisms.—G. F. Garton.

LIN, T. M., KARVINEN, E. and IVY, A. C. **Capacity of the rat intestine to absorb cholesterol.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 422–423. [Dept. Clin. Sci., Univ. Illinois Coll. Med., Chicago.]

Four groups of 6 rats received the same amount of basal fat-free diet plus 2 g. oleic acid every second day for 40 days. Three groups were given a daily supplement of 96, 192 or 288 mg. cholesterol. Faecal cholesterol level showed that the amount of cholesterol absorbed reached a plateau when the intake was 192 mg. per 250 g. rat daily.

HERNANDEZ, H. H., CHAIKOFF, I. L. and KIYASU, J. Y. **Role of pancreatic juice in cholesterol absorption.** *Amer. J. Physiol.*, 1955, **181,** 523–526. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

The common bile duct of male rats was cannulated at the duodenal junction and a second cannula was inserted into the duodenum for the introduction of secretions from donor rats; a third cannula was introduced into the thoracic duct to permit collection of lymph. Cholesterol labelled with ^{14}C was given by stomach tube to these rats and the extent of intestinal absorption was judged by the recovery of ^{14}C from the lymph.

The rats lost the capacity to absorb cholesterol, and this was not restored by continuous administration of pancreatic juice through the duodenal cannula. The administration of bile alone brought about some absorption of labelled cholesterol, but much less than in control animals. Normal cholesterol absorption was established when bile and pancreatic juice were given together. Homogenates of duodenum prepared from animals with diverted pancreatic secretion gradually lost the capacity to esterify cholesterol; after 24 hr., when the rats were no longer able to absorb cholesterol, the esterifying power of duodenal tissue was almost nil.—G. A. Garton.

MNUKHINA, E. S. O potreblenii fosfatidov i kholesterina pri myshechnoi rabote. [**The utilisation of phosphatides and cholesterol in muscular work.**] *Fiziol. Zh. SSSR Sechenova*, 1955, **41**, 89–94. [Nauch.-Issled. Inst., Leningrad.]

Phospholipin and cholesterol were estimated: on blood samples from athletes taken before and after different periods and types of severe exercise; on frog gastrocnemius muscle after electrical stimulation; on the blood and gastrocnemius muscle of cats after stimulation of the peripheral end of the cut sciatic nerve; and on rat liver, muscle, brain and blood after swimming. In all experiments a brief period of muscular work was associated with a rise, and a prolonged period with a fall in both phospholipin and cholesterol value. This is held to indicate utilisation of these substances in prolonged work.—D. W. Taylor.

ZILVERSMIT, D. B., MCCANDLESS, E. L. and SHORE, M. L. **Phospholipide metabolism in various tissues of cholesterol-fed rabbits.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 48–51. [Div. Physiol., Univ. Tennessee, Memphis.]

Two groups of rabbits were fed on 100 g. rabbit chow daily for 5 months; in addition the experimental group received 1 g. cholesterol dissolved in 2·8 g. fat daily. All animals then received an intravenous injection of 0·5 to 1·0 mC. ^{32}P in labelled phosphate; 6 hr. later they were killed and samples of blood, organs and tissues were taken for extraction of phospholipins and assay of their ^{32}P activity.

The rabbits given cholesterol showed greater incorporation of ^{32}P into the phospholipins of aorta, plasma and liver, but not in lung, small intestine, kidney and muscle. The livers of the cholesterol group showed a greater increase in tissue mass than was caused by fatty infiltration; a possible relation between phospholipin turnover and fatty infiltration is discussed.—G. A. Garton.

RICE, C. E., DUHAMEL, L. and GIRARD, A. **The effect of prolonged injection of ethionine on rabbits and guineapigs fed a high cholesterol diet. 1. On complement titre.**

PLUMMER, P. J. G., BOULANGER, P., CORNER, A. H. and RICE, C. E. **2. On the development of pathological lesions.**

RICE, C. E., BOULANGER, P. and DUHAMEL, L. **3. On serum lipids.** *Canad. J. Comp. Med.*, 1955, **19**, 167–171; 201–212; 256–263. [Div. Animal Pathol., Canada Dept. Agric., Animal Dis. Res. Inst., Hull, Que.]

1. When guineapigs received repeated subcutaneous injections of ethionine a decline in complement titres occurred whether or not the stock pellet diet was supplemented with cholesterol. Complement titres of guineapigs given cholesterol but not treated with ethionine were comparable to those of control animals on the same diet.

In rabbits injected repeatedly with ethionine for 7 weeks to 6 months the complement titre also fell, but less in animals given cholesterol than in those given the stock diet. Higher complement titre was found in rabbits given cholesterol but not injected with ethionine; this increase was frequently to levels higher than those in controls given the stock ration.

2. None of the ethionine-treated rabbits on the stock diet showed atheromatous lesions of the aorta and vessels of the heart, but similarly treated animals given cholesterol showed after $3\frac{1}{2}$ to 6 months lesions similar in extent and distribution to those in rabbits given cholesterol but no ethionine. Guineapigs in similar studies showed no atheromatous lesion of the aorta or heart vessels.

3. Total lipids, cholesterol and lipid P were estimated in serum from the rabbits and guineapigs described above. In the guineapigs treated with ethionine, serum total lipids and cholesterol were lower than in untreated animals given corresponding diets. Treatment with ethionine had no effect on the serum cholesterol of rabbits on the stock diet, but appeared to reduce cholesterol values in animals given cholesterol. The lipid P content of the pooled sera of both groups of rabbits treated with ethionine tended to be slightly higher

than that of the corresponding controls on the same diet.—G. A. Garton.

759

SHORE, M. L., ZILVERSMIT, D. B. and ACKERMAN, R. F. **Plasma phospholipide deposition and aortic phospholipide synthesis in experimental atherosclerosis.** *Amer. J. Physiol.*, 1955, **181,** 527–531. [Div. Physiol., Univ. Tennessee, Memphis.]

Plasma containing phospholipins labelled with ^{32}P was injected intravenously into 6 normal rabbits and 6 given cholesterol. After 2, 4, 6 and 10 hr. blood samples were taken, then the rabbits were killed and the entire thoracic aorta and 5 g. liver were taken for analysis.

The concentration of phospholipins in the aortas of the animals given cholesterol was about 126 per cent. greater than normal. The differences in phospholipin content of the whole aorta were even greater, with an increase of about 440 per cent. The deposition of plasma phospholipins accounted for a tenth or less of the phospholipins present in the atheromatous thoracic aortas.—G. A. Garton.

WILGRAM, G. F., BEST, C. H. and BLUMENSTEIN, J. **Aggravating effect of cholesterol on cardiovascular changes in choline deficient rats.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 476–479. [Banting and Best Dept. Med. Res., Univ. Toronto.]

Groups of rats were fed on high-fat choline-deficient diets with 1, 2 or 4 per cent. cholesterol. The cholesterol increased the incidence of cardiovascular lesions. The significance of kidney damage in the etiology of the condition is discussed. When choline was incorporated in the diet containing 4 per cent. cholesterol, no significant change in the cardiovascular system was found, although the fat content of the liver rose. The role of choline in the production of experimental arteriosclerosis is discussed.—G. A. Garton.

NICHOL, J. T. **The effect of cholesterol feeding on the distensibility of the isolated thoracic aorta of the rabbit.** *Canad. J. Biochem. Physiol.*, 1955, **33,** 507–516. [Dept. Biophys., Univ. W. Ontario, London.]

An apparatus is described for measuring the pressure-volume relations of the isolated aorta of the rabbit. It was demonstrated that in young rabbits fed on cholesterol there was destruction of elastic tissue in the aorta during development of atherosclerosis, so that the vessel was more distensible at low pressures; at pressures above 70 mm. Hg the effect of the loss of elastic tissue was masked by the presence of proliferated collagenous tissue.—G. A. Garton.

763

WELLS, W. W., COLEMAN, D. L. and BAUMANN, C. A. **Intestinal sterols. 1. Δ^7-Cholestenol and 7-dehydrocholesterol in feces.** *Arch. Biochem. Biophys.*, 1955, **57,** 437–444. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Chromatography of the unsaponifiable matter of faeces from rats on a fat-free diet showed the presence of Δ^7-cholestenol, cholesterol, coprosterol and 7-dehydrocholesterol. Substantial amounts of Δ^7-cholestenol were identified in the faeces of man, dog and guineapig; 7-dehydrocholesterol was present in guineapig faeces, but only traces were found in human and dog faeces. The sterol content of the faeces of rats was not altered by a variety of dietary constituents including fats, dextrin, lactose, squalene and sulphasuccidine. It is concluded that much of the faecal Δ^7-cholestenol and 7-dehydrocholesterol originates in the intestinal mucosa.—G. A. Garton.

764

KANDUTSCH, A. A. and BAUMANN, C. A. **Skin sterols. 9. Effect of squalene on the sterols of mouse skin.** *Arch. Biochem. Biophys.*, 1955, **56,** 356–362. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Chromatographically purified squalene was given as 1 or 2 per cent. of a synthetic diet to groups of rats and mice for 1 or 2 days, and a 30 per cent. solution of squalene in acetone was applied daily or thrice weekly, 4 drops each time, to the backs of young adult mice for up to 3 weeks.

Dietary squalene did not affect the amount of Δ^7-cholestenol in the livers of rats or mice. Analysis of skin lipids showed that the application of squalene to the skin of young mice resulted in an accumulation of Δ^7-cholestenol and cholesterol in the epidermis; the skin of adult mice, which normally contains more Δ^7-cholestenol, was less sensitive to squalene.—G. A. Garton.

SUR, B. K. and SUBRAHMANYAN, V. **Utilization of calcium and phosphorus in the poor rice diet supplemented with lucerne or milk powder.** *Indian J. Med. Res.*, 1955, **43**, 231–235. [Central Food Technol. Res. Inst., Mysore.]

Weanling rats were divided into 4 groups of 8. Three groups were given modifications of a basal diet of polished rice 78·5, tur dhal (*Cajanus indicus*) 5, fat 5, non-leafy vegetables 8·2, leafy vegetables 2·1, whole milk powder 0·9 and NaCl 0·3 per cent.; in the experimental diets rice, 5 per cent., was replaced by whole milk powder, equal quantities of whole milk powder and tender lucerne-leaf flour, or lucerne alone. The rats received the diets for 4 weeks and were killed and analysed for body Ca and P; initial body Ca and P were estimated in the fourth group at the beginning of the experiment.

The percentages of Ca and P in the newly-weaned rats and those on the milk, milk plus lucerne and lucerne diets, in that order, were 0·72 ± 0·014, 0·59 ± 0·012, 0·62 ± 0·014, 0·68 ± 0·009 and 0·536 ± 0·008, 0·45 ± 0·006, 0·45 ± 0·008, 0·48 ± 0·006.—G. F. Garton.

FLÜCK, P. Ein Beitrag zum Einfluss von Fluor auf die Calciumausscheidung bei der Milchziege. [**The effect of fluorine on the excretion of calcium by the lactating goat.**] *Thesis, Univ. Berne*, 1955, pp. 21.

A lactating goat received by stomach tube every other day, for a total of 10 doses, 100 ml. of Ca lactobionate solution containing ^{45}Ca. It was fed on oats, with hay to appetite, and was milked once daily. The ^{45}Ca activity was estimated daily in milk and blood until it had almost disappeared. The experiment was then repeated, but the goat received by tube, as well as the ^{45}Ca and at a different time of day, 5 mg. NaF in water daily. Since the goat drank about 4 litres of water daily, this was equivalent to 1·25 mg. NaF per litre.

Except on the first day on which ^{45}Ca was given, the milk was always more radio-active than the blood. The activity in the blood was always low and sometimes absent on the days on which no ^{45}Ca was given, but that in the milk was usually higher on these days. When the ^{45}Ca was withdrawn the blood was almost inactive in 2 days, but milk activity declined slowly for 2 weeks.

When NaF was given there was no adverse effect on appetite or milk yield. The ^{45}Ca activity in the blood was increased and the output in the milk in the first 21 days was double that in the corresponding days without NaF. When the ^{45}Ca was withdrawn the activity of the milk declined more slowly. Most of the activity in milk was in the casein fraction.—D. Duncan.

HOGAN, A. G., HOUSE, W. B. and REGAN, W. O. **Effect on guinea pigs of consuming an excessive quantity of phosphates.** *Univ. Missouri Agric. Exp. Stat. Res. Bull.* No. 567, October 1954, pp. 8.

A colony ration supplying 1·2 per cent. Ca and 0·9 per cent. P proved satisfactory for growth and reproduction of guineapigs, although animals over 18 months old sometimes developed sore and stiff joints with visible deposits of calcium phosphate. When the P was increased to 1·6 per cent. for 6 guineapigs, all developed stiffness within about 16 weeks and 5 had deposits of calcium phosphate within about 19 weeks. Guineapigs grew more slowly when fed on a synthetic diet containing about 1 per cent. each of Ca and P than on the colony ration, and 2 of 15 animals had deposits. When P in this diet was increased to 1·65 per cent. growth was depressed still more and 30 of 41 animals had deposits.—A. Hepburn.

770

CLARKE, E., EVANS, B. M., MACINTYRE, I. and MILNE, M. D. **Acidosis in experimental electrolyte depletion.** *Clin. Sci.*, 1955, **14**, 421–440. [Dept. Med., Postgrad. Med. Sch., London.]

In 10 experiments on 3 healthy men the effects of administration of ammonium chloride with a normal diet and during NaCl and K depletion were studied. Each experiment lasted 5 to 7 days, with an interval of at least 3 weeks on a normal diet between successive experiments. During K depletion 1 g. NaCl was taken 4 times a day; during NaCl depletion 1 g. anhydrous K_2HPO_4 was taken 4 times a day. Ammonium chloride was taken as 6 doses, each of 2 g., evenly spaced during waking hours. The low K diet used has been described previously (Abst. 4885, Vol. 24); the Kempner rice diet was used for NaCl depletion and a preliminary intramuscular injection of 2 ml. Mersalyl was given to increase NaCl excretion. Analyses of urine were made; the faecal output of electrolytes was found to be negligible.

In NaCl deficiency the capacity of the kidney to synthesise and excrete ammonia was reduced, but the *p*H of urine was normal. In K deficiency there was impaired ability to secrete urine of maximum acidity, but ammonia excretion was normal. It was confirmed that ammonia excretion depends on both urine *p*H and systemic acid base balance.

771

KRNJEVIĆ, K., KILPATRICK, R. and AUNGLE, P. G. **A study of some aspects of nervous and muscular activity during experimental human salt deficiency.** *Quart. J. Exp. Physiol.*, 1955, **40,** 203–216. [Dept. Physiol., Univ. Edinburgh.]

Salt depletion was produced in 2 men by a low-salt diet and sweating under a hot cradle for an hour twice daily for 10 days. The diet consisted mainly of salt-free bread and margarine, lean meat, potatoes, fresh fruit and green vegetables cooked without salt, and provided about 3000 Cal., 70 g. protein and 16 m. equiv. Na daily. Fluid intake was at least 3 litres daily.

The symptoms of salt deficiency were as described by McCance (Abst. 997, Vol. 6). Weight losses were 4 and 4·5 kg. Plasma Na fell from 134 to 121 m. equiv. per litre in one subject and from 136 to 128 in the other. The diuretic response to a water load was reduced. There was no change in gastric emptying time. There was no significant change in maximum work performed on a fly-wheel or in time of muscular contraction. Differences in the refractory period of the ulnar nerve and decrease in the height of muscle action potential during high frequency stimulation were found in one subject. In the encephalogram the only change, seen in both subjects, was a slight fall in mean alpha frequency.

It was concluded that the quantitative changes in nervous and muscular activity are probably too small to be detected without studying a large number of subjects.—D. Duncan.

772

RENWICK, R., ROBSON, J. S. and STEWART, C. P. **Observations upon the withdrawal of sodium chloride from the diet in hypertensive and normotensive individuals.** *J. Clin. Invest.*, 1955, **34,** 1037–1043. [Dept. Clin. Chem., Univ. Edinburgh.]

Six normal subjects and 6 patients with high blood pressure were given a low-sodium diet supplying 8 m. equiv. Na daily with NaCl added in amounts from 3 to 6 g. daily. Excretion of electrolytes became stable in from 4 to 5 days and, after it had been so for from 7 to 14 days, the salt was withdrawn. Estimations of bodyweight change, volume of urine and amounts of Na, K and Cl in urine and blood serum and of N in urine showed no significant difference between the groups. In all subjects after removal of the salt bodyweight fell during the first 48 hr. and output of K in urine rose, the balance of K being negative usually for a week and in 1 subject for 18 days. There was no associated rise in excretion of N. It is suggested that the change in metabolism of K was due to an increase in adrenocortical activity immediately after salt was withheld.—D. Harvey.

HORVATH, B., BERG, L., CUMMINGS, D. J. and SHY, G. M. **Muscular dystrophy. Cation concentrations in residual muscle.**

BERG, L., EBAUGH, F. G. (Jr.), SHY, G. M., HORVATH, B. and CUMMINGS, D. J. **Blood content of dystrophic muscles.**

SHY, G. M., CUMMINGS, D. J., BERG, L. and HORVATH, B. **Potassium exchange in residual muscle.** *J. Appl. Physiol.*, 1955, **8,** 22–30; 31–32; 33–36. [Branch Med. Neurol., Nat. Inst. Health, Bethesda, Md.]

In the first paper the Na and K contents of residual muscle fibres were calculated on the basis of estimations of total water, total Na and K, intracellular water and blood content of tissue obtained by biopsy. In the text and in an addendum the methods and their theoretical implications are described and discussed in detail. Samples of tissue were taken from 20 patients and from 4 control subjects. In the diseased compared with normal conditions the total and intracellular water contents of muscle were low; in muscle fibres the intracellular K was low and the intracellular Na high. The correlation between fall in concentration of K and rise in that of Na was significant.

A simple method with radio-active isotopes ^{42}K and ^{51}Cr or ^{131}I is described for estimating blood in biopsy specimens of muscle. The volume of blood in dystrophic did not differ from that in normal muscle.

Patients with muscular dystrophy and normal subjects were given ^{42}K by mouth and urine samples were collected for 22 hr. afterwards. In

the patients the means for amounts exchanged, 1095 and 597 m. equiv., respectively, were less than the mean, 1731 m. equiv. for the control subjects. At the end of the 22 hr., biopsy specimens of muscle were removed and examined by the above technique. An index of turnover of K in muscle, which was calculated from these data, was found in the dystrophic patients to be within the same range as for the normal subjects.

D. Harvey.

FINBERG, L. and HARRISON, H. E. **Hypernatremia in infants. An evaluation of the clinical and biochemical findings accompanying this state.** *Pediatrics*, 1955, **16**, 1–14. [Div. Paediat., Baltimore City Hosps., Md.] Spanish and Interlingua summaries.

An analysis was made of findings in 88 infants in whom concentrations of Na in serum were over 150 m. equiv. per litre. In 69 of these infants the cause of admission to hospital was diarrhoea. Mortality was 11·6 per cent., compared with just under 2 per cent. in a group of 205 children with severe diarrhoea and serum Na values below 150 m. equiv. per litre. Age distribution was not significantly different in the 2 groups, but there were more premature infants in the group with high serum Na. All the patients with high serum Na had a history of acute curtailment of water intake. In about two-thirds of them there was evidence of injury to the nervous system. Low serum Ca often accompanied high Na.

In the treatment of the condition the best results were obtained by the administration of fluids with a total Na concentration of from 15 to 40 m. equiv. per litre.—F. C. Aitken.

NATELSON, S. and ALEXANDER, M. O. **Marked hypernatremia and hyperchloremia with damage to the central nervous system.** *Arch. Int. Med.*, 1955, **96**, 172–175. [Labs., Rockford Mem. Hosp., Ill.]

In patients with brain damage high plasma Na and Cl values may persist despite adequate hydration. Two illustrative cases are reported and the dangers of prolonged treatment with non-saline fluids are emphasised.—F. C. Aitken.

776

GREEN, D. M., REYNOLDS, T. B. and GIRERD, R. J. **Effects of diet, salt intake and salt-loading on tissue sodium concentration and turnover.** *Amer. J. Physiol.*, 1955, **181**, 97–104. [Sch. Med., Univ. S. California, Los Angeles.]

The tissue Na concentration was expressed in terms of the ratio of the concentration in the tissue to that in the plasma, T : P ; the advantages of the comparison are discussed.

Adult rats were fed on Purina chow and water to appetite except during experiments. The low-salt diet in experiments lasting not more than 2 weeks was pure Lonalac, but for longer experiments sucrose, minerals and vitamins were added. For high salt intake this diet was supplemented with 0·86 per cent. saline instead of drinking water. ^{22}NaCl was given intraperitoneally or in the drinking water. The turnover of ^{22}Na in muscle after 2 weeks of low-Na diet was very slow ; after 2 weeks of high Na intake it was rapid. The T : P ratio was little affected. In rats given the high Na intake and then injections of ^{22}Na the soft tissues were analysed up to 12 days after the injection for ^{22}Na and ^{23}Na. For the first 96 hr. the distribution of ^{22}Na was similar to that of ^{23}Na, except that the former was higher in kidney and liver. After 96 hr. the T : P ratio of ^{22}Na fell. In longer experiments in which ^{22}NaCl was given in the drinking water the distribution of ^{22}Na in the soft tissues took more than 2 weeks to become constant, but from the third to the 14th week it changed little. The T : P of bone increased throughout the 14 weeks, but at the end equilibrium was near. It is suggested that all bone Na is completely exchangeable when sufficient time is allowed. High concentrations of ^{22}Na in whole bone were due to concentrations in the bone cortex, not so much to marrow.—D. Duncan.

TOBIAN, L. (Jr.) (with WHITE, L.) **Effect of a low sodium diet on electrolyte composition of arterial wall.** *Amer. J. Physiol.*, 1955, **181**, 599–601. [Dept. Biol. Chem., Harvard Med. Sch., Boston, Mass.]

Fourteen control rats were given to appetite a diet of water and rat chow containing 0·3 per cent. Na ; 10 similar rats received a diet containing 0·003 per cent. Na with all essential vitamins and minerals. After 5 weeks the rats were killed and their aortas were removed for analysis.

The rats on the low-Na diet had 12 per cent. less Na in their aortas on a dry weight basis than the control rats ; this difference was significant. The decrease in aorta Na on the low-Na diet was accompanied by a very slight rise in serum Na. The aortas of the rats on the low-Na diet had a significantly higher P content than the aortas of the control rats. There was no significant difference between the two groups in water, K or Mg content of the aorta. The average blood pressure of rats on the low-Na diet was 10 mm. Hg lower than that of controls ; this difference was not significant.—G. F. Garton.

778

BERGSTROM, W. H. **The participation of bone in total body sodium metabolism in the rat.** *J.*

Clin. Invest., 1955, **34,** 997–1004. [Dept. Paediat., New York State Univ. Coll. Med., Syracuse.]

Seven rats were depleted of Na and made acidotic by peritoneal lavage with a solution of NH_4Cl and glucose until about 25 per cent. of the estimated total body Na was removed. The rats were then allowed water but no food for 48 hr. during which urine was collected and analysed for Na, after this they were killed and bone, blood and defatted carcase were analysed. Another 14 rats had stock diet and for 13 or 16 days were given acetazoleamide in the drinking water at the rate of 666 mg. per litre. Serum *p*H was studied. Six of these rats were then treated by lavage like the first group. Seven more rats after lavage and fasting for 48 hr. received intraperitoneally in 2 doses 200 ml. per kg. bodyweight of a solution containing, in m. equiv. per litre, Na 150, Cl 100 and HCO_3^-/50, and were killed after 24 hr. Another 9 after lavage and fasting were allowed 5 days on chow and water to appetite and were killed when they had regained 86 per cent. of the weight lost after lavage. Carcases of 20 controls on stock diet were analysed.

In the 48 hr. after lavage the total urine Na was less than 1 m. equiv. per kg. bodyweight daily. Of the total Na loss of 10·8 m. equiv. per kg., 28 per cent. was lost from extra bone Na (*i.e.*, that in excess of the amount predictable from Cl concentration), 20 per cent. from intracellular and 52 per cent. from extracellular Na. After acidosis produced by acetazoleamide total body composition was normal, but bone Na fell as much as after lavage and was not further reduced by subsequent lavage. During repair, whether this resulted from intraperitoneal administration of electrolytes or from normal feeding, there was no increase in bone Na, and apparently little or no Na retention could be ascribed to bone.—D. Duncan.

779

MUNTWYLER, E. and GRIFFIN, G. E. **Tissue electrolyte content of potassium and protein-deficient rats.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 349–352. [Dept. Biochem., Coll. Med., State Univ. New York.]

Apart from a slightly low plasma K concentration, rats fed for 5 weeks on a diet deficient in protein and K had no pronounced difference from normal in tissue electrolyte composition. Supplementing the diet with K restored the plasma K, but did not significantly affect the tissue electrolytes. The rats were in negative K and N balance.

When protein was added to the deficient diet there was a positive N balance and a growth response, but not as much as when K also was added. Chloride, Na and K balances were negative. The concentration of K fell in plasma, kidney, heart muscle and liver and especially in skeletal muscle. The calculated total K in liver and kidneys increased, but insufficiently to account for the loss from skeletal muscle and that not excreted.—A. Hepburn.

HISSINK, L. A. G. De waarde van physiologische zoutoplossing en combinaties daarvan met glycose-oplossingen voor de behandeling van post-traumatische shock. [**Value of physiological saline alone or with glucose solution for the treatment of post-traumatic shock.**] *Nederland. Tijdschr. Geneesk.*, 1955, **99,** 2500–2505. [Prince Henry Hosp., Sydney.] English summary.

No agreement has been reached on the treatment of post-traumatic shock with isotonic saline solution. Glucose solutions or casein hydrolysate solutions are not recommended. The fear of pulmonary oedema seems unfounded in saline treatment after shock, and is probably due to the occurrence of this complication in patients with heart disease. Of 111 rats given traumatic shock the controls all died within 10 hr. Of those given saline infusion, 0·9 per cent. NaCl, 57 per cent. died in 10 hr., 81 per cent. in 24 hr. Two other groups were given saline plus 5 per cent. glucose and saline plus glucose plus 0·4 per cent. KCl. Their mortality rates were, respectively, 93 per cent. after 10 and all after 24 hr., and 86 and 91 per cent. Saline therefore seemed to give the best results without addition of glucose.—M. Eddison.

782

HUANG, K. C. **Effect of salt depletion and fasting on water exchange in the rabbit.** *Amer. J. Physiol.*, 1955, **181,** 609–615. [Dept. Physiol., Coll. Phys. Surg., Columbia Univ., New York.]

In 26 experiments on 16 rabbits the effect of salt depletion and food deprivation on water intake and urine output was studied. Extracellular electrolytes were depleted by intraperitoneal lavage, which produced immediate and profound depression lasting 24 to 48 hr. in all the animals; they usually stopped eating and drank less. Their plasma chloride level and plasma volume were reduced; the plasma protein level was raised. Of 11 rabbits given a low-salt diet all but one showed thirst and polyuria. Of 8 fasted

animals, all showed a gradual increase in plasma chloride and Na and 4 increased their water intake and urine output.—G. F. Garton.

BURNETT, G. W. **The effect of fluorides on the organic and inorganic components of intact dentin.** *J. Dent. Res.*, 1955, **34**, 489–502. [Dept. Dent. Res., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

Sections of dentine were made from extracted human teeth which had not been exposed to fluoride during development. They were treated under standardised conditions for 144 hr. with solutions of NaF, CaF_2 or PbF_2 or of potassium or calcium monofluorophosphate and then with a decalcifying acid, lactic, acetic, butyric, citric, succinic, formic, nitric or hydrochloric, for 24 hr. Loss of weight was estimated and the accessibility of the organic matrices of the dentine was measured by the author's method (Burnett and Scherp, *J. Dent. Res.*, 1952, **31**, 776).

In general NaF was most effective, PbF_2 was sometimes nearly as effective as NaF and CaF_2 was least effective in preventing loss of weight; accessibility of the organic matrix was greater in treated than in untreated teeth when organic acids were used, but less with inorganic acids.—D. Harvey.

784

WADHWANI, T. K. **Effect of fluorine on the composition of bones: changes in the composition of bones of monkeys (*Macaca radiata*).** *Indian J. Med. Res.*, 1955, **43**, 321–330. [Sect. Pharmacol., Indian Inst. Sci., Bangalore 3.]

Pairs of monkeys were given a diet of bread, groundnuts and a cake prepared from wheat flour, casein, sugar, yeast, salts and fat, with water to appetite, for 27 weeks. Each animal received daily one banana weighing 70 to 90 g. and containing 5 to 8 mg. vitamin C; one of each pair received daily 10 mg. NaF per kg. bodyweight. At the end of the experiment the monkeys were X-rayed. The experimental animals showed distinct thickening of the periosteum and formation of exostoses; animals which showed gross changes in the bones were killed with their controls and their bones were analysed for N, carbonate, Ca, P, Mg, Na and K; the exostoses of humerus, tibia and femur were removed and analysed separately. Results are tabulated.

Four monkeys with severe bone fluorosis were given a normal diet and the administration of F was discontinued; 2 of them were given 20 mg. ascorbic acid daily for 12 weeks. X-ray examination then revealed that in the animals given ascorbic acid exostoses were almost absent from the bones. The bones of all 4 animals were analysed as before.—G. F. Garton.

785

MILLER, R. F. and PHILLIPS, P. H. **Effect of feeding fluoroacetate to the rat.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 411–413. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Groups of 4, 5 or 10 weanling rats were allowed, to appetite, water and a basal diet of ground whole wheat, ground yellow maize, dried skimmed milk, soya bean meal, linseed meal, alfalfa leaf meal, melted butter, $CaCO_3$ and iodised salt. Sodium monofluoroacetate was ground in sucrose and incorporated into the basal diet to give the required intake. The first experiment was designed to estimate tolerance for fluoroacetate; in the second experiment the tolerance under different conditions was tested, and the adaptability of the rat to larger increments of fluoroacetate.

The rats survived the addition of 20 p.p.m. fluoroacetate to the diet; this level first caused retardation in growth, but after 3 to 4 weeks nearly complete recovery of the growth rate was evident. Rats which had received 20 p.p.m. fluoroacetate became conditioned to further increases, which produced only transitory fluctuations in the growth rate; this conditioned tolerance to fluoroacetate was lost within 2 weeks. Administration of fluoroacetate caused increased storage of F in the femur.—G. F. Garton.

786

ARIZONO, H. and ICHIKAWA, M. **Histochemical studies on the changes of calcium and alkaline phosphatase in experimental dental and bone fluorosis of rats.** *Med. J. Osaka Univ.* (Engl. Ed.), 1955, **6**, 205–216. [Dept. Pub. Health, Wakayama Med. Coll.]

Five groups, each of 5 or 6 male rats aged about 60 days, were given daily, with food, 15 to 20 ml. NaF solution which provided 1, 5, 10, 50 or 100 p.p.m. F; a sixth group was maintained on a fluorine-free diet. After 107, 192 or 210 days the rats were killed and histochemical studies were made of the lower jaw and femur.

Alkaline phosphatase of the pulp and periodontal membrane of the molar teeth decreased or disappeared in proportion to the amount of F administered. With increasing F content calcification of the enamel was unchanged, but the dentine, cement and alveolar bone presented a gradually increasing Ca reaction. In the periosteum, Haversian and Volkmann's canals and epiphyseal plate of the femur phosphatase activity fell after high intakes of F and was little changed at low intakes. In the endosteum and bone marrow

there was no quantitative difference in phosphatase activity. There was less enzyme activity after low levels of F intake when the experimental period was long. Ca reaction of the bone shafts, trabeculae and epiphyseal plate was negative at low F intakes and positive at high intakes, the Ca reaction being proportional to the F concentration; prolonged F intake caused a positive Ca reaction even at low levels.—G. F. Garton.

HARRIS, N. O. and HAYES, R. L. **A tracer study of the effect of acute and chronic exposure to sodium fluoride on the thyroid iodine metabolism of rats.** *J. Dent. Res.*, 1955, **34**, 470–477. [Dent. Sci. Div., U.S. Air Force Sch. Aviation Med., Randolph Air Force Base, Randolph Field, Tex.]

Ten adult female rats were divided into 2 groups of 5. The 5 controls were anaesthetised and injected intraperitoneally with 1 ml. saline solution containing 250 μC. ^{131}I. Gamma radiation counts were recorded every min. for 10 min. thereafter. The second group was similarly treated except that 0·33 ml. of 1·25 per cent. NaF in saline was injected intraperitoneally simultaneously with the ^{131}I, on the opposite side of the abdomen. There was no significant difference in ^{131}I uptake between the 2 groups.

In the second experiment there were 4 groups, each of 6 male and 6 female rats. All were given the Remington iodine deficient diet (Abst. 645, Vol. 7) for 35 days, during which they had access to demineralised water containing no F or 10, 50, or 100 p.p.m. NaF. At the end the rats were injected with 1 ml. of saline solution containing 1 μC. ^{131}I. After 24 hr. each was anaesthetised and bled out. Thyroids were weighed and the radio-activity was estimated in thyroids and in plasma. There was no significant difference between the 4 groups. Autoradiographs of thyroid tissue demonstrated that I was concentrated in the colloid no matter what the F intake.

ALLCROFT, R., SALT, F. J. and HIGNETT, S. L. **The effect of commercial phenothiazine on blood iodine values in sheep.** *Vet. Rec.*, 1955, **67**, 626–630. [Vet. Lab., Minist. Agric., Weybridge, Surrey.]

The percentage of total I in 8 commercial samples of phenothiazine ranged from 0·4 to 0·0004. Abnormally high total plasma I values in sheep were associated with administration of even a single dose of 20 g. phenothiazine with a high I content, and these did not fall to normal for about 3 weeks. After such treatment the uptake of radio-active I was greatly reduced, although protein-bound I values were raised only very slightly.

It is suggested that continuous excess of circulating plasma I due to these phenothiazine preparations high in I may have a deleterious effect on physiological functions in the sheep.

B. W. Simpson.

NEWBURGER, R. A., SILVER, S., YOHALEM, S. B. and FEITELBERG, S. **Uptake and blood level of radioactive iodine in hyperthyroidism.** *New Engl. J. Med.*, 1955, **253**, 127–130. [Andre Meyer Dept. Phys., Mount Sinai Hosp., New York.]

Each of 96 untreated hyperthyroid patients and 404 normal euthyroid subjects was given by mouth a tracer dose of ^{131}I consisting of 25 to 100 μC. carrier-free ^{131}I in 100 ml. water. The ^{131}I present in the thyroid 24 hr. later was measured and the uptake was recorded as percentage of the dose, allowing for decay. Venous blood was drawn 72 hr. after the same tracer dose and 4 ml. serum or plasma was placed in a well-type crystal scintillation counter. If 0·27 per cent. or more of the dose was found per litre of plasma, thyrotoxicosis was suspected and protein-bound ^{131}I was estimated.

By this technique it was shown that there was little overlap of the values for protein-bound ^{131}I in the plasma of euthyroid subjects and thyrotoxic patients, but in the uptake studies the overlap was much greater. The former method was, therefore, a more helpful diagnostic aid. Statistical examination of the results showed that by the protein-bound ^{131}I technique 1·6 per cent. of errors in classification occurred, compared with 7·2 per cent. by the ^{131}I uptake method.

B. W. Simpson.

GILBERT, J. L. and LANGE, G. **Renal clearance of I^{131} in hypothyroid and euthyroid rats.** *Endocrinology*, 1955, **57**, 181–183. [Dept. Physiol., Coll. Med., State Univ., New York.]

Male rats had their thyroids removed. Half of the animals were given daily 5 μg. L-thyroxine parenterally. The rats receiving thyroxine had almost normal pulse rates and the hypothyroid rats had rates slower by 50 to 100 beats per min. For estimation of renal clearance 10 μC. ^{131}I were injected intraperitoneally 2 to 3 weeks after thyroidectomy, and 1 ml. blood was taken by cardiac puncture under anaesthesia half an hour after injection. The rats were then placed in urine collecting jars and 24 hr. later a second blood sample was taken and the urine was measured. The activities of samples of serum and urine were estimated by Geiger Müller tube and scaler. The mean renal clearance rate of the 33 hypothyroid rats was only two-thirds that of the 34 euthyroid rats; the difference was statistically significant. The average renal clearance rate of rats thyroidectomised 1 to 3 days before the test was the same as

that of rats operated on 2 to 3 weeks earlier. It is emphasised that the influence of renal clearance rate of ^{131}I on plasma level should be considered in studies concerning thyroid uptake and thyroid activity.—B. W. Simpson.

IRON AND COPPER

791

BIELIG, H. J. and BAYER, E. Eisenaustauch zwischen Proteinen; Modellversuche zur Eisenresorption und -speicherung im Tierkörper. **[Iron exchange among proteins; model experiments on absorption and storage of iron in the animal organism.]** *Naturwissenschaften*, 1955, **42,** 466. [Max-Planck-Inst. Med. Forsch., Heidelberg.]

Ferritin formed *in vitro* from ferrous ions, apoferritin and CO_2 in bicarbonate CO_2 buffer at *p*H 7·2 (see Bielig and Bayer, *Naturwissenschaften*, **42,** 125) will give up its Fe at *p*H 5·5 to 7·5 in the presence of excess ascorbic acid, glutathione or dihydrocodehydrase I. The Fe^{+++} was taken up across a cellophane membrane by siderophilin, giving an example of exchange of Fe between 2 proteins *in vitro*.—D. Duncan.

792

SALERA, U. and TAMBURINO, G. Eisenaufnahme, Eisenreserve und Hämoglobinsynthese. **[Iron absorption, iron reserve and haemoglobin formation.]** *Deutsch. med. Wochenschr.*, 1955, **80,** 933–934. [Ist. Patol. Med., Univ. Rome.]

From the rate at which Fe labelled with ^{55}Fe and given by vein is taken up by blood-forming tissues, it is concluded that part of this Fe is used at once for Hb formation, without being converted first to storage Fe. The Fe used for Hb formation, corresponding in quantity with the 24 mg. set free daily by physiological haemolysis, comes partly from " exogenous " and partly from stored sources.

D. Duncan.

793

SMITH, N. J., ROSELLO, S., SAY, M. B. and YEYA, K. **Iron storage in the first five years of life.** *Pediatrics*, 1955, **16,** 166–173. [Dept. Paediat., Sch. Med., Univ. California, Los Angeles.] Spanish and Interlingua summaries.

Iron, total and in the water-insoluble form in haemosiderin, was estimated in liver tissue *post mortem* from 58 children under 5 years of age. The water-soluble Fe could not satisfactorily be separated into Hb and ferritin fractions. The data are presented for 5 age groups, 0 to 6, 6 to 12, 12 to 24, 24 to 40 and 40 to 60 months, at which ages the mean values were for total Fe 1305, 922, 358, 581 and 798, and for water-insoluble Fe 541, 491, 154, 339 and 378 μg. per 10 g. tissue. Attempts to estimate storage in living children by staining bone marrow with Prussian blue were unsuccessful. The fall in Hb seen in the first 2 months of life is associated with the large stores and the incidence of deficiency anaemia in the second year can be linked with the small stores of Fe in the liver at these ages.—D. Harvey.

794

JEFFREY, M. R., FREUNDLICH, H. F., JACKSON, E. B. and WATSON, D. **The absorption and utilization of radioiron in rheumatoid disease.** *Clin. Sci.*, 1955, **14,** 395–406. [Royal Nat. Hosp. Rheumatic Dis., Bath.]

Absorption of ^{59}Fe from one large dose or from repeated smaller doses was studied in patients with rheumatoid arthritis and the hypochromic anaemia which is often refractory to treatment with Fe by mouth, but which responds to Fe given parenterally. Estimations were made of ^{59}Fe in blood and faeces; control subjects were patients undergoing similar treatment for diseases known not to affect haemopoiesis. No evidence was found that failure of absorption of Fe either causes or perpetuates the condition or is the reason for its resistance to treatment with Fe given by mouth.

D. Harvey.

795

KINNEY, T. D., KAUFMAN, N. and KLAVINS, J. **Effect of ethionine-induced pancreatic damage on iron absorption.** *J. Exp. Med.*, 1955, **102,** 151 – 156. [Dept. Pathol., Cleveland City Hosp., Ohio.]

There were 2 experiments. In the first, 5 groups of rats received a synthetic diet to appetite or in restricted amount or with additions of ferric citrate, 2 per cent., or *dl*-ethionine, 0·5 per cent., or both. In the 2 ethionine groups damage to pancreas and to liver was seen histologically and both microscopic and chemical tests indicated that deposition of excess Fe had occurred. The mean values for Fe content in mg. per 100 g. liver for the groups in the above order were 14·6, 25·9, 21·1, 35·3 and 55·8. Corresponding total amounts of Fe were 1·6, 1·6, 2·1, 2·9 and 5·7 mg. In the second experiment 2 groups of mice were fed on the same diet without or with 0·5 per cent. ethionine; total Fe was estimated in body as well as in liver. The findings were, on the average, 32·4 and 79·0 mg. per 100 g. liver, and for total amounts in liver 0·5 and 0·9 mg. and in body 1·9 and 2·3 mg.

Damage to the exocrine cells of the pancreas resulted in increased absorption and deposition of Fe in the liver and not merely in a shift of Fe from endogenous sources.—D. Harvey.

FEASTER, J. P., HANSARD, S. L., MCCALL, J. T. and DAVIS, G. K. **Absorption, deposition and placental transfer of zinc^{65} in the rat.** *Amer. J. Physiol.*, 1955, **181,** 287–290. [Nutrit. Lab., Florida Agric. Exp. Stat., Gainesville.]

Forty-four adult nulliparous female rats were maintained on a stock diet and given, at stages of pregnancy ranging from the ninth to the twenty-first day, a single oral or intraperitoneal dose of $^{65}ZnCl_2$. Balance studies were made for the next 96 hr.; the animals were then killed and the foetuses were removed. These, as well as maternal blood, whole body tissues, urine and faeces were analysed for total and radio-active Zn.

The absorption of the ^{65}Zn from the digestive tract was poor, but there was relatively free transfer across the placenta to the foetuses at all stages of gestation. In a study on the mammary transfer of ^{65}Zn, with 8 female rats and their litters, 57 per cent. of the retained portion of the ^{65}Zn was transferred through the milk to the young during 96 hr. In maternal tissues ^{65}Zn content was proportional to total Zn; the kidney had the highest content, followed in order by liver, pancreas and femur. The transfer of total Zn to foetuses was proportional to that of ^{65}Zn; the foetal content of both ^{65}Zn and total Zn increased throughout gestation and reached a maximum at term.

METABOLISM OF WATER

801

POLITZER, W. M., BARRY, M. E. and KING, A. **The effect of heat stress on mine workers with regard to loss of water and electrolytes.** *S. African J. Med. Sci.*, 1954, **19,** 155–160. [Dept. Biochem., S. African Inst. Med. Res., Johannesburg.]

The subjects were 81 African miners aged between 18 and 40 years who volunteered for examination at the end of working shifts of 8 hr., in conditions for which mean data were dry bulb temperature 86° F., wet bulb temperature 84° F., relative humidity 92 per cent. and average cooling power 13·3 millicalories per sec. From examinations of abdominal skin and of orbits no evidence of dehydration was found; sweat rash, seen in 9 subjects, suggested profuse sweating; muscular tenderness suggesting cramp was not noted. Blood examinations for urea, Cl, Na, K, total proteins and packed cell volume gave results within normal range, and a more intensive examination of 19 subjects before, and immediately and 18 hr. after, work showed no haemoconcentration. Records of losses of fluid indicated that dehydration was mild and temporary in nature.

KOZIĆ, LJ. Prilog ispitivanju funkcionalne sposobnosti bubrega konja. [**The function of the kidney in the horse.**] *Acta vet., Belgrade*, 1955, **5**, No. 1, 83–95. [1. Int. Clin., Vet. Fac., Belgrade.] German summary.

Horses were starved for 2 days to produce conditions comparable to those in human subjects fasted overnight. Water loads of 22 ml. per kg. bodyweight were given by stomach tube. No advantage was found from greater loads, up to 88 ml. per kg.

Water diuresis began in the second hour and was greatest in the third, fourth and fifth. After this the volume of urine began to fall and its sp. gr. to rise. The horses were given oats and the return of the sp. gr. to normal was studied.

Such studies are considered to offer a diagnostic method for kidney disorders in horses.

803

LE MAGNEN, J. Le rôle de la réceptivité gustative au chlorure de sodium dans le mécanisme de régulation de la prise d'eau chez le rat blanc. [**Role of the taste threshold for sodium chloride in the mechanism for regulation of water intake in the white rat.**] *J. Physiol., Paris*, 1955, **47**, 405–418.

Adult rats received a standard ration for an hour once daily. At first they were offered water 7, 5 and 3 hr. before feeding, for an hour each time, and their water intake was recorded. The first offer of water was then replaced by 2 per cent. NaCl solution given on alternate days to drink or the same amount by stomach tube, and water intake was again recorded 2 and 4 hr. later. On the average the water intake was 60 per cent. greater after saline had been drunk than after it had been given by tube. The difference was highly significant. Only when saline was drunk did intake significantly exceed the control amount.

When the saline was replaced by isosmotic, 12 per cent., glucose solution, rats which drank the solution refused all water offered 2 and 4 hr. later. When the solution was given by tube they drank as much as rats given saline by tube. When water was given by tube it did not affect the amount drunk 2 and 4 hr. later.

Rats given saline by tube had saline applied to the dorsal surface of the tongue for several seconds, and this stimulated them to drink in the next 20 min., but they compensated by drinking less afterwards, so that in 3 hr. there was no difference between their intake and that of rats given saline by tube alone.

It is concluded that taste receptors affect the regulatory mechanism controlling water intake after administration of saline solutions.

D. Duncan.

REID, M. E. **Nutritional studies with the guinea pig. 3. Choline.** *J. Nutrition*, 1955, **56**, 215–229. [Lab. Biochem. Nutrit., Nat. Insts. Health, Pub. Health Serv., Bethesda, Md.]

Groups of 8 guineapigs aged 2 to 4 days were given a semi-synthetic diet containing vitamin-free casein 30, fat 7·3 and salts 6 per cent., with 4 types of carbohydrate and liberal amounts of the known vitamins but no choline. Different levels of choline, from 0·2 to 5 g. per kg. diet, were added and after 6 weeks the animals were killed and the internal organs were examined. Similar studies were made with different compounds used as substitutes for, or supplements to, choline.

The omission of choline from the diet resulted in severe retardation of growth, weakness of muscles, reduction in the number of red blood cells, lower haematocrit and Hb values, small subcutaneous and adrenal haemorrhages and paleness of the kidneys, without severe kidney haemorrhage or much fatty infiltration of the liver; survival time was 21 to 67 days. The inclusion of small amounts of choline in the diet produced a chronic state of deficiency characterised by slight retardation of growth, anaemia and great muscle weakness. From 1 to 1·5 g. choline chloride per kg. diet gave 100 per cent. survival and maximum growth.

Neither betaine nor methionine was an effective substitute for choline, but both had a supplementary value when added to a suboptimum level of choline. Dimethylaminoethanol was the only compound equal in effect to choline when administered on a molar basis. Neither methylaminoethanol nor methionine improved growth or survival when used with the choline-deficient diet, but together

in suitable amounts they were as effective as choline chloride.—G. F. Garton.

806

KNUDSON, A. and HARRIS, R. **Observations on blood pressure and tissue cholesterol following choline deficiency in weanling rats.** *J. Nutrition*, 1955, **56**, 295–301. [Dept. Biochem., Albany Med. Coll., Union Univ., Albany, N.Y.]

Rats aged 3 weeks were given 3·6 mg. choline per 100 g. diet for 5 days; pair-fed controls received the same diet plus 350 mg. choline per 100 g. Thereafter the animals were given a stock diet for 3 to 7 months. Other rats were given a choline-free diet (Abst. 823, Vol. 21) for 3 to 7 months.

The rats briefly given the low-choline diet had an average arterial blood pressure of 108 mm. Hg; only 14 out of 71 had mean arterial pressures above 124 mm. Hg. Of the 69 rats on the choline-free diet, only 24 had mean arterial pressures above 124 mm. Hg, the average for this group being 133 mm. In animals with high blood pressure there was no significant change in total and free cholesterol in plasma, aorta, heart, kidney and liver. Renal lesions, slight or severe, were found in 37 out of 70 rats on the choline-free diet.—G. F. Garton.

METABOLISM OF CELLS, TISSUES, ETC.

GENERAL PHYSIOLOGY

807

HEALY, G. M., FISHER, D. C. and PARKER, R. C. **Nutrition of animal cells in tissue culture. 10. Synthetic medium No. 858.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 71–77. [Connaught Med. Res. Labs., Univ. Toronto.]

The 62 ingredients, which include 3 antibiotics, and the system of combining them are described. The tissue cells with which nine- and tenfold increases in 7 days are reported are L strain cells from the mouse (Sanford *et al.*, *J. Nat. Cancer Inst.*, 1948, **9**, 229). The medium with 20 per cent. horse serum added is being used by the authors for the propagation of all strains of cell.—D. Harvey.

808

EAGLE, H. **The specific amino acid requirements of a mammalian cell (strain L) in tissue culture.** *J. Biol. Chem.*, 1955, **214**, 839–852. [Sect. Exp. Therap., Pub. Health Serv., U.S. Dept. Health, Bethesda, Md.]

The cells were of the L strain of mouse fibroblast, grown in a monocellular layer on a glass surface. The basal medium contained 19 amino-acids, the known vitamins, inorganic salts, choline, glucose, glutamine, glutathione and inositol and was supplemented with 0·25 to 2 per cent. of dialysed horse serum. In this medium cultures could be maintained for as much as 8 weeks without change in growth rate or appearance of the cells.

By omitting them from the medium in turn it was shown that arginine, cystine, histidine, *iso*-leucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, tyrosine and valine were essential for survival and growth. Alanine, aspartic acid, glutamic acid, glycine, hydroxyproline, proline and serine were not essential; it is unlikely that the small amount of serum protein in the medium was supplying them. The cytological effects of deficiency of any one essential amino-acid were reversible for 2 to 6 days. The concentrations of essential amino-acids needed for maximum growth varied from 0·005 μmole tryptophan per ml. to 0·1 or 0·2 μmole *iso*leucine per ml., and below these concentrations the rate of growth fell sharply. None of the 12 essential L-amino-acids could be replaced by the D-isomer, but the D-isomers did not actively inhibit growth.

Although the cultures required 12 amino-acids, arginine, cystine and tyrosine are not essential for the mouse.—D. Duncan.

809

KIENY, M. Les besoins nutritifs spécifiques des tibias d'embryon de poulet en culture *in vitro* sur milieux synthétiques. [**Specific nutrient requirements of the tibia of the chick embryo cultured *in vitro* on synthetic media.**] *C.R. Soc. Biol.*, 1955, **149**, 418–421.

For earlier experiments see Abst. 4302, Vol.23; Kieny *et al.*, *C.R. Acad. Sci.*, 1954, **239**, 1426.

The linear growth and survival of tibias were studied in media containing 3 to 5 amino-acids; the basal medium contained cysteine, methionine, arginine, histidine, lysine, glutamic acid and *p*-aminobenzoic acid. Growth was retarded when arginine, methionine, glutamic acid, or lysine plus histidine was omitted. Augmentation of growth occurred when cysteine, lysine or histidine was omitted.

In a medium with arginine, methionine, glutamic acid, histidine and *p*-aminobenzoic acid growth was 93 per cent. better than in the basal medium.

The basal medium was improved by addition singly of serine, threonine, asparagine, taurine and

hydroxyproline. Linear growth of tibia was accelerated but survival was reduced by valine, glutamine or tyrosine. Survival was improved, but growth was not, by alanine, glycine, glutathione, phenylalanine, ornithine or *iso*leucine. Leucine, tryptophan, proline and aspartic acid were valueless or detrimental.—D. Duncan.

NEWEY, H., SMYTH, D. H. and WHALER, B. C. **The absorption of glucose by the *in vitro* intestinal preparation.** *J. Physiol.*, 1955, **129,** 1–11. [Dept. Physiol., Univ. Sheffield.]

The loss of glucose in preparations of rat's small intestine *in vitro* during the transport of glucose across the mucosal surface was examined. Lactic acid was the main metabolite and was formed in sufficient quantity to account for 50 to 70 per cent. of the glucose lost, and carbon dioxide could account for about another 25 per cent. Some evidence was obtained, from experiments with glucose labelled with ^{14}C, of the production of a keto-acid; this was not identified, but was presumed to be pyruvic acid.—A. T. Phillipson.

812

BLOOM, B., EISENBERG, F. (Jr.) and STETTEN, DEW. (Jr.) **Glucose catabolism in liver slices via the phosphogluconate oxidation pathway.** *J. Biol. Chem.*, 1955, **215,** 461–466. [Div. Nutrit. Physiol., Pub. Health Res. Inst. City of New York, Inc.]

Glucose, gluconate and ribose, all labelled with ^{14}C, were incubated with rat liver slices and the radio-activity of CO_2, fatty acids and glycogen was estimated. The results suggest that some of the glucose was catabolised via phosphogluconate.
A. Hepburn.

813

BLOOM, B. and STETTEN, D. (Jr.) **The fraction of glucose catabolized via the glycolytic pathway.** *J. Biol. Chem.*, 1955, **212,** 555–563. [Div. Nutrit. Physiol., Pub. Health Res. Inst. City of New York, Inc.]

Glucose, gluconate and lactate, all labelled with ^{14}C, were incubated with liver slices from normal rats and the radio-activity of CO_2 and fatty acids was estimated. About half the glucose was considered to be catabolised via the Embden Meyerhof pathway, *i.e.*, via glucose-6-phosphate and fructose-6-phosphate to lactate.—A. Hepburn.

TAUPITZ, A. Histochemische Untersuchungen an Gewebekulturen über den Kohlenhydratstoffwechsel der Zelle in Abhängigkeit vom Kaliumgehalt des Nährmediums. [**Histochemical studies with tissue cultures of the carbohydrate metabolism of the cell as related to the potassium content of the culture medium.**] *Arch. exp. Pathol. Pharmakol.*, 1955, **226,** 197–206. [Pathol. Inst., Akad. Med. Forsch., Justus Liebig Hochsch., Giessen.]

The tissue cultured was spleen from adult guineapigs or rats. The basal culture medium contained, per cent., extract of 9-day chicken embryos 25, Tyrode solution 25 and plasma from fasted guineapigs or rats 50. The mineral content, per cent., was K 0·03, Na 0·32 and Ca 0·009, the K concentration being about 30 per cent. above that in normal plasma. K was added in different experiments as aqueous KCl or $KHCO_3$ to give concentrations of 0·01, 0·02, 0·03 and 0·05 mole per litre. Growth experiments lasted 48 hr.

Even at 0·01 mole the K caused a perceptible decrease in growth of cultures from both species, and at 0·03 and 0·05 mole the inhibition was considerable. There was little glycogen in normal cultures, but addition of 0·02 mole K was followed by deposition of much glycogen in rounded-off fibroblasts. With more K there was again little glycogen.

Dehydrase, detected by the reduction indicator triphenyltetrazolium chloride, was not affected by 0·01 mole K, but was reduced by 0·02 mole and much reduced or absent with higher concentrations. The same was true for alkaline phosphatase.
D. Duncan.

PEETERS, G., SIERENS, G., TINDAL, J. and COUSSENS, R. Échanges de sucres dans le pis de vache isolé et perfusé. [**Sugar exchanges in the isolated perfused udder of the cow.**] *Arch. internat. Pharmacodyn.*, 1955,

102, 470–475. [Lab. Physiol., École Vét., Univ. Ghent.] English summary.

Halves of isolated udders were perfused with 8 litres of oxygenated, heparinised whole blood to which was added sodium acetate, 15 g. in 250 ml. water, or glucose, 10 g. in 250 ml. water. In control experiments nothing was added. Blood samples were examined for sugars by paper chromatography before and after perfusion for 90 to 120 min.

The whole blood always contained glucose and fructose initially, and these sugars partly or completely disappeared during perfusion. Lactose always appeared during perfusion, and galactose in one experiment. The quantities of glucose which disappeared were from 2300 to 8870 mg. (the higher values after addition of glucose), of fructose 85 to 355 mg., and the quantities of lactose which accumulated were from 693 to 4240 mg.

The mammary vein blood of 2 cows within a few hours after calving contained 2·2 and 3 mg. lactose per cent.—D. Duncan.

817

BASSIR, O. **A pathological study of the effect of low-protein diet on liver cell metabolism.** *West African Med. J.*, 1955, **4,** 78–91. [Area Pathol. Lab., Westwood Hosp., Beverley, Yorks.]

The livers of rats after 4 days of a protein-free diet were compared with those of rats on a diet with 27 per cent. casein. In the deprived animals the water content of the liver was unchanged; there was a non-significant increase in the neutral fat and a significant decrease in the N content of neutral-fat-free tissue, which was evidence of a decrease in labile cytoplasm. Histological examination showed no change in the size of the liver cells, but the mitochondria were arranged round the nucleus and at the periphery of the cells, and masses of glycogen filled the vacuoles caused by this rearrangement, though the animals had been starved for 6 hr. before death. Ribonucleic-acid-bearing particles in the cytoplasm were less concentrated in the protein-starved than in the normal rats. Studies with radio-active tracers confirmed the loss of labile protein and ribonucleic acid from the cytoplasm in the protein-starved rats and showed an increase in the amount and activity of deoxyribonucleic acid per g. liver. After one day of the high-casein diet the changes in the liver caused by protein deprivation were reversed.

818

FRITZ, I. (with BERECH, J. (Jr.)). **Studies on the incorporation and release of N^{15} by tissue proteins of rats fed N^{15}-glycine. 1. The protein metabolic activity of salivary glands. 2. The activities of muscle, oral mucosa, and incisor pulp proteins.** *J. Dent. Res.*, 1955, **34,** 435–445; 446–451. [Dept. Dent. Res., Dent. Div., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

1. Rats received a diet containing, per cent., casein 15, maize starch 47, lard 23, Wesson oil 4, cod liver oil 2, brewer's yeast 5 and salt mixture 4. After about 2 weeks they were given 1 ml. of 2·5 per cent. solution of glycine labelled with ^{15}N, twice daily for 3 days. Then half were fed and killed after 18 or 161 hr. and half were fasted and killed after from 10 to 161 hr. Selected tissues were extracted in cold trichloroacetic acid and protein and N.P.N., and their ^{15}N content, were estimated.

The ^{15}N content of salivary gland proteins declined with time after the last dose of ^{15}N, especially in rats allowed to eat. Liver protein had always a higher ^{15}N concentration than salivary gland protein. The submaxillary gland protein had a slightly higher ^{15}N concentration than parotid gland protein. Submaxillary glands lost over 25 per cent. of their total protein N during the first 90 hr. of fasting and later regained some N, but parotid protein N was maintained at first and declined mainly after 90 hr.

2. The decline in ^{15}N activity in proteins from the gingival mucosa, palatal mucosa and tongue membranes was very rapid; that in incisor pulp proteins was about equal to that in liver. Although all skeletal muscles studied took up a little ^{15}N, the greatest concentration was reached in tongue muscle. The high ^{15}N uptake and rapid turnover in oral mucosa are thought to reflect the rapid regeneration of the tissues.—D. Duncan.

MORGAN, J. F. and MORTON, H. J. **Studies on the sulfur metabolism of tissues cultivated *in vitro*. 1. A critical requirement for L-cystine.** *J. Biol. Chem.*, 1955, **215,** 539–545. [Lab. Hyg., Dept. Nat. Health Welfare, Ottawa.]

Chick embryonic heart fibroblasts survived for about 35 days in a synthetic medium containing sulphur amino-acids, but only for 8 to 12 days in their absence. L-Cystine, but not L-methionine, increased the time of survival. Both were required

for survival for 35 days. L-Cystine could be almost replaced by cysteine and to a smaller extent by lanthionine, ergothioneine, oxidised glutathione, cystathionine or 2 : 3-dimercaptopropanol.

DIANZANI, M. U. **Content and distribution of pyridine nucleotides in fatty livers.** *Biochim. biophys. Acta*, 1955, **17**, 391–405. [Lab. Physiol. Chem., Univ. Utrecht.] French and German summaries.

The content of pyridine nucleotides in experimentally induced fatty livers from rats was below normal, particularly in the mitochondria. In homogenates the pyridine nucleotides were displaced into the supernatant fluid. The loss and displacement of diphosphopyridine nucleotide and the reduced oxidation of substances requiring it occurred before fat accumulated within the cells.

HAUSBERGER, F. X. and MILSTEIN, S. W. **Dietary effects on lipogenesis in adipose tissue.** *J. Biol. Chem.*, 1955, **214**, 483–488. [Dept. Anat., Jefferson Med. Coll., Philadelphia, Pa.]

Adipose tissue was obtained from male rats which had been fasted or fed on a stock diet, high-fat diets or low-fat diets. The tissue was incubated with ^{14}C-labelled glucose as described by Hausberger *et al.* (*J. Biol. Chem.*, 1954, **208**, 431); the radio-activity of the CO_2 evolved and the fatty acids formed was measured.

Fasting or a high-fat diet abolished formation of fatty acid by adipose tissue, and the oxidation of glucose was greatly diminished.

The administration of protamine zinc insulin for 60 hr. to animals receiving the stock diet increased the production of ^{14}C-labelled fatty acids and $^{14}CO_2$; this effect was much less in animals on high-fat diets.

Fatty acid production from carbohydrate appears to be regulated not only by the carbohydrate content of the diet. Glucose utilisation increased as the carbohydrate content of the diet increased or as the fat content decreased.—G. A. Garton.

824

MAYER, J., HAGMAN, N. C., MARSHALL, N. B. and STOOPS, A. J. **Fat metabolism in three forms of obesity. 5. Hepatic lipogenesis *in vitro*.** *Amer. J. Physiol.*, 1955, **181**, 501–503. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

See also Absts. 5292, Vol. 25; 738, Vol. 26.

Liver slices were prepared from mice with hereditary obesity and diabetes or mice rendered obese by goldthioglucose injections and from hypothalamic hyperphagic rats. The slices were incubated at 37·5° C. for 3 hr. in the presence of ^{14}C-carboxyl-acetate; incorporation of ^{14}C into liver fat was then studied.

The slices from all 3 forms of obese animals incorporated more ^{14}C-acetate into lipids, expressed both per liver and per g. fat-free tissue, than their controls. Similar experiments with fasting animals showed less incorporation of ^{14}C into liver lipids; the rate of liver fat formation was depressed in mice fasted after goldthioglucose to the same low values as were found in the non-obese controls, but the rate observed in the livers of genetically obese mice, though depressed, was twice that found in their corresponding controls. The results suggest a distinction between regulatory and metabolic types of obesity (See Vol. 25, p. 607).

ESKELSON, C. D., FIRSCHEIN, H. E. and JENSEN, H. **Effect of thyrotropin administration on the *in vitro* uptake and conversion of I^{131} and release of organic-bound I^{131} by the isolated thyroid gland.** *Endocrinology*, 1955, **57**, 168–172. [Dept. Biochem., Army Med. Res. Lab., Fort Knox, Ky.]

Male rats weighing from 205 to 270 g. were injected intraperitoneally with 5 U.S.P. units of thyroid-stimulating hormone in 1 ml. saline, 3, 6, 12, 24 or 42 hr. before they were killed. Controls were given saline alone. The thyroids were incubated at 37° C. for 4 hr. in 2 ml. Krebs buffer with 1 μC. ^{131}I. Distribution of ^{131}I in the gland and in the fluid was studied.

At 3, 6 or 12 hr. the isolated thyroid from rats given hormone did not concentrate or convert ^{131}I to the same extent as glands from the controls, but 24 hr. after administration of hormone the glands seemed to regain their capacity to concentrate ^{131}I to the same extent as those of controls. At 36 hr. the differences between control and experimental glands were inconsistent, but at 42 hr. there was indication of an increase in total and organic ^{131}I in the glands of the treated rats. The decrease of activity of the glands 3, 6 and 12 hr. after administration of hormone is interpreted as being caused by the increase of thyroid hormone in the blood.—B. W. Simpson.

CARTIER, P. and PICARD, J. La minéralisation du cartilage ossifiable. 1. La minéralisation du cartilage *in vitro*. [**Mineralisation of ossifiable cartilage. 1. Mineralisation of cartilage *in vitro*.**] 2. Le système ATPasique du cartilage. [**2. The adenosine triphosphatase system of cartilage.**] *Bull. Soc. Chim. biol.*, 1955, **37**, 485–494; 661–675. [Fac. Méd., 149 Rue de Sèvres, Paris.]

1. Thin slices of cartilage were prepared from the carpal and tarsal bones of sheep embryos of 1500 to 3000 g. bodyweight. Mineralisation was studied in solutions containing different proportions of Ca and of P as orthophosphate or organic compounds.

No mineralisation occurred in the absence of organic P compounds, and mineralisation was negligible with a Ca : P ratio of 2 and P in the form of glucose-1-phosphate, fructose-1 : 6-phosphate, phospho-2-glyceric acid or β-glycerophosphate. Considerable mineralisation occurred only when the P was in the form of adenosine triphosphate (ATP). The results are opposed to those of Robison (*Biochem. J.*, 1923, **17**, 286) and of Gutman *et al.* (Abst. 1418, Vol. 12).

2. Mineralisation in solutions containing ATP was prevented after heating to 60° C. and much reduced after heating to 50° C. The optimum *p*H was about 8·0 to 8·2. Mineralisation increased with ATP concentration up to 10 mg. per 100 ml. Mineralisation at first increased with time, but almost reached its limit within 24 hr. unless successive additions of ATP were made. It was similar in aerobic and anaerobic conditions. The presence of Mg was essential, but at high concentrations it was inhibitory. F was without effect. Cysteine and ascorbic acid were inhibitory, HCN slightly so at concentrations greater than 0·002 *M*. Hydrogen peroxide and iodine were without effect except in concentrations high enough to cause protein denaturation. Low K concentrations reduced mineralisation. Histidine had a favourable effect. Phloridzin was inhibitory.

ATP could not be replaced by acetylphosphate, phosphocreatine, phosphoenolpyruvic acid, cocarboxylase or similar P compounds. The enzyme was not readily extractable. It was partly inactivated by formalin, completely by sodium nitrite.

The enzyme differs in properties from bone alkaline phosphatase and its localisation in the epiphyseal cartilage is different.—D. Duncan.

ODEBLAD, E. and ZILIOTTO, D. **Accumulation of radioactive phosphate in epithelia.**

ZILIOTTO, D. and ODEBLAD, E. **A study on the uptake of P^{32} in several organs of anemic rats.** *Acta pathol. microbiol. scand.*, 1955, **37**, 150–152; 153–156. [Dept. Gynaecol., Sabbatsberg Hosp., Karolinska Inst., Stockholm.]

Most epithelial linings in a number of mammalian species studied, and also epithelial derivatives such as salivary glands and hair follicles, take up ^{32}P more readily than connective tissue and muscle.

In rats made anaemic by repeated bleeding some of the epithelia, such as those of the digestive tract, took up less ^{32}P than those of normal rats. The red pulp of the spleen and also the adrenals appeared to take up more ^{32}P than was normal.

D. Duncan.

PIGMAN, W., HAWKINS, W. L., WATSON, J., POWELL, R. and GASTON, C. **The effect of the concentration of D-glucose on the attack of tooth substances in the artificial mouth.** *J. Dent. Res.*, 1955, **34**, 537–545. [Dent. Sch., Univ. Alabama, Birmingham.]

Extracted teeth were mounted in plastic boxes and treated with a bacteriological medium containing, per cent., 0·5 tryptone, 0·2 yeast extract and 0·025 $CaHPO_4 . 2H_2O$ at *p*H 6·4, to which different amounts of glucose were added. In some experiments dentine was decalcified before exposure with a buffered solution of sodium lactate. With glucose in relatively high concentration, 0·5 per cent., the effect was mainly decalcification of dentine; dentine already decalcified was softened and, in time, completely destroyed. With a lower concentration, 0·25 per cent., of glucose both

decalcification and destruction of dentine matrix occurred; in a few months dentine, enamel and cement of sound teeth were extensively destroyed.

In bacteriological studies after inoculation with pooled samples of saliva of known streptococcus and lactobacillus counts it was found that streptococci reached maximum growth when the glucose concentration was 0·25 per cent., and that lactobacilli required the same concentration for survival.—D. Harvey.

The human carcinoma cell, like the mouse fibroblast (see Abst. 808, Vol. 26) required the 8 essential amino-acids plus arginine, cyst(e)ine, histidine and tyrosine for growth. Degenerative changes and death followed the absence of any of these, but the early changes could be reversed by addition of the missing amino-acid. The D-enantiomorphs had no apparent effect. The minimum and optimum concentrations for growth varied with the amino-acid. High concentrations of at least 6 separate amino-acids inhibited growth.

BERNFIELD, P. and HOMBURGER, F. **The influence of tumor growth on the plasma proteins in mice.** *Cancer Res.*, 1955, **15,** 359–364. [Cancer Res. and Cancer Control Unit, Dept. Biochem., Sch. Med., Tufts Univ., Boston, Mass.]

Plasma proteins from 85 normal and 126 tumour-bearing mice were analysed by micro-electrophoresis. α-Globulin had considerably increased 4 days after the implantation of tumours, while the tumour nodules were still hardly palpable, and reached a maximum after 8 to 14 days and then declined. Albumin remained constant until the tenth day, when it began to decline. In one experiment total plasma protein fell greatly during tumour growth. α-Globulin rose by about 50 per cent., albumin fell by about 40 per cent. and the changes in β- and γ-globulins were not significant.

WARD, D. N. and GRIFFIN, A. C. **Phosphorus incorporation into nucleic acids and proteins of liver nuclei of normal and azo dye-fed rats.** *Cancer Res.*, 1955, **15,** 456–461. [Dept. Chem., Stanford Univ. Sch. Med., Calif.]

Rats received for 6 to 8 weeks a purified diet with or without 0·06 per cent. of 3′-methyl-4-dimethylaminoazobenzene, which usually requires 12 to 15 weeks to produce liver tumours. The controls gained more weight than those given the dye. At the end of this time each rat received an intraperitoneal injection of ^{32}P as phosphate; they were killed between $\frac{1}{2}$ and 18 hr. later. The liver nuclei were isolated and fractionated.

There was no difference in uptake of ^{32}P by the nuclear ribonucleic acid between the groups. Adenylic acid took up more ^{32}P than the other constituent nucleotides.—D. Duncan.

OBERHAUSER, F. B., CROXATTO, H. R., GAILLARD, M. Q. and SILVA, V. M. **Anti-tumorigenic action of iodinated compounds.** *Nature*, 1955, **176,** 466–467. [Lab. Chem., Fac. Phil. Educat., Univ. Chile.]

Rats received by oesophageal tube 3 daily doses of a solution containing 0·482 *M* KI and 0·083 *M* KIO_3, equivalent to 43 mg. I per 100 g. bodyweight every 24 hr. This treatment, begun on the same day as or 2 weeks before the implantation of spindle cell sarcoma in 19 rats, caused inhibition of tumour growth and complete disappearance of tumour in 70 per cent. [exact number not given] of the rats. Large tumours developed in 21 control rats, which died. In another experiment, of 38 rats treated 45 days before implantation of the sarcoma and 38 control rats, 34 in each group developed tumours. All the treated rats were alive after 64 days and there was no trace of tumour, but the 34 control rats died with large tumours.—A. Hepburn.

Effect of internal and external influences on the growth processes.**] *Førsogslab. København Beretn.*, 1955, No. 282, pp. 190. English summary.

For an account of most of the practical work described here see Abst. 5421, Vol. 25. Here the derived philosophical concepts also are elaborated. The hyperbolic function of age holds so long as the metabolic gradient does not suffer a qualitative change; any quantitative change is shown only in change of the constant Q, which is therefore a measure of the absolute level of the activity of synthesising enzymes. There are reasons to associate such activity with the mitochondria and it follows that (since mitochondria will then have a critical size above which they either become less active or subdivide) activity and number of mitochondria in living cells are probably synonymous. It is argued from this that the growth constant Q is a function of the absolute concentration of mitochondria in self-reproducing cells, which also falls as the mitochondria are distributed over increasing numbers of descendent cells.

It follows that no external agent can alter the constant Q unless it can enter as a component of the mitochondrial enzyme system. For instance, penicillin was found to alter the Q of protein and P deposition in pigs. On the assumption that there might be bacteriostatically inactive but

physiologically active split-products, *e.g.*, SH^- groups which might catalyse the turnover of active acetyl, perhaps in Lipmann's coenzyme A, experiments were made with dimercaptopropanol (BAL), aminoethylmercaptan and phenylthiodiazolethionsulphydrate. All three reproduced the effect of penicillin which is, therefore, thought to be independent of any effect on the gut microflora. The effect is probably a general mercaptan effect, which penicillin shares, and depends on building a sulphydryl group into the coenzyme A system with a speeding-up of the synthetic processes in the Krebs cycle.

Normal growth of young pigs, birth to 180 days, proceeds with a series of changes of Q, *i.e.*, abrupt increases in number of mitochondria, which resemble mutations.—I. Leitch.

848

THOMSON, J. **Observations on weight gain in infants.** *Arch. Dis. Childhood*, 1955, **30**, 322–327. [Dept. Child Life and Health, Univ. Edinburgh.]

The infant population of a clinic was sampled at ages 2 weeks ± 2 days; 4, 8, 16, 20 and 24 weeks, ± 3 days; 28, 32 and 36 weeks, ± 5 days; 40, 44, 48 and 52 weeks, ± 7 days. Birthweights were available for all the infants. A total of 1737 observations on boys and 1605 on girls were made and from the data the mean birthweights and the mean weight gains with their standard deviations for each sex at each age were calculated. The inquiry was confined to single legitimate infants of birthweight 5½ to 9½ lb.

The results confirmed that throughout the first year the mean weight gain is greater in boys than girls. Apart from a doubtful and slight relationship in the early weeks of life, the correlation coefficients between birthweight and postnatal weight gain were not of statistical significance. The data did not substantiate the prevalent idea that birthweight is doubled and trebled at certain ages. It is suggested that graphs of infant weight should be begun at zero on the birthday so that only gains and losses of weight are recorded thereafter. Comparison of the mean weight at 1 year, undifferentiated for sex, with data published in 1926 showed an increase of about 2 lb. over the earlier data. Examination of weight charts in use in local authority infant welfare clinics indicated that they are outmoded.—F. C. Aitken.

849

THOMSON, J. **Infant size at six months.** *Health Bull., Dept. Health Scot.*, 1955, **13**, 46–48.

For 130 boys and 106 girls born in Edinburgh Royal Infirmary the respective means and standard deviations at about 2 and 26 weeks were: weight in oz. 122·8 ± 14·6, 277·9 ± 27·2, and 117·4 ± 15·3, 262·6 ± 27·9; crown-heel length in inches 20·5 ± 0·74, 26·2 ± 0·72, and 20·1 ± 0·85, 25·6 ± 0·76; crown-rump length 13·7 ± 0·60, 17·4 ± 0·57 and 13·5 ± 0·61, 16·9 ± 0·53; occipitofrontal circumference 14·3 ± 0·45, 17·3 ± 0·47, and 13·8 ± 0·47, 16·9 ± 0·45. Many were first babies, but since the separate results for first-born and subsequent infants did not differ significantly, the data were combined. The weight and crown-heel length at 26 weeks exceed the Edinburgh Welfare Clinic norms, set up 30 years ago, by about 2½ lb. and 0·85 in., and it is considered that there is need for a large-scale study of infant growth to provide new norms of weight and length. There were positive correlations between weight at birth and at 26 weeks and between all 3 linear measurements at 2 weeks and 26 weeks and negative correlations, significant only for linear measurements, between early values and increments to 26 weeks. Boys increased more in weight and in length than girls, but for occipito-frontal circumference there was no sex difference.—W. M. Deans.

850

PROVIS, H. S. and ELLIS, R. W. B. **An anthropometric study of Edinburgh schoolchildren. 1. Methods, data and assessment of maturity.** STEIN, L. **2. Comments on results.** *Arch. Dis. Childhood*, 1955, **30**, 328–337; 432–438. [Dept. Child Life and Health, Univ. Edinburgh.]

1. Measurements of recumbent crown-heel length, crown-rump length and span; erect bi-acromial diameter and intraspinous pelvic width; unclothed weight; head length, breadth and circumference, and estimates of maturity, were made, mostly by a single observer in 1951–52, on 1730 Edinburgh schoolchildren between the ages of 5 and 18, from 2 primary and 3 secondary mixed state schools and 4 fee-paying schools, 2 for boys and 2 for girls. Full details of measuring technique are given. Maturity in boys was estimated by criteria previously set up (Abst. 2264, Vol. 17); girls were reckoned pubescent when early signs of breast development were found and adolescent when menstruation began. Mean values, standard deviations and coefficients of variation of the 9 body measurements are tabulated for boys and girls separately for each year of age, and crown rump length : length and span : length ratios and cephalic index are also given. Some of the results are presented graphically [other graphs are in the second part].

Between the ages of 11 and 14, girls were longer than boys; at younger ages sex differences were not consistent, and it is suggested that the measurement of recumbent length might eliminate the small differences usually found in erect height.

The median ages of pubescence and adolescence were 13·45 and 15·35 years for boys and 11·30 and 13·35 years for girls. There was some indication that pubescence in boys lasts longer in those who begin early, but not in those who begin late. There is evidence that the age of menarche in Edinburgh is significantly earlier than it was 50 years ago. The data are compared with other British and American results.

2. The results are discussed in more detail, with additional graphs. For crown-heel length the coefficients of variation were mostly about 4 to 5 per cent., *i.e.*, most of the children in each age group had lengths within 10 per cent. of the group mean. The same was true of several other body measurements. Their variability increased slightly for ages from about 12 to 16. Head measurements were much less variable and there was no age effect on variability, presumably because much of the head growth has already occurred before the age of 5. Weight was much more variable than linear measurements. Generally speaking, the boys' means formed a more regular pattern than those of the girls. Whether this is due to greater variability in girls or to less consistent measuring of girls by a male investigator is not clear.

W. M. Deans.

851

SAITO, K. and TSUJI, T. **Birth weight and subsequent physical development. 2. School age periods.** *Bull. Inst. Pub. Health, Tokyo*, 1954, **4,** No. 1/2, Japanese pp. 20–23; English p. 20. [Dept. Maternal and Child Health.]

In continuation of the previous report on preschool children (Abst. 2426, Vol. 25) a study was made of Japanese schoolchildren aged from 7 to 10 years. The subsequent development of the 4 birthweight groups, less than 2·5 kg., from 2·5 to 3·0 kg., from 3·0 to 3·75 kg., and 3·85 kg. or more, was followed by making 5013 measurements of weight and 4082 of height. The close relation between birthweight and subsequent weight was again apparent for both sexes. No clear relation between birthweight and subsequent height was established. The subsequent growth and height of the premature group contrasted sharply with those of the next higher birthweight group in boys but not in girls; no explanation could be obtained from the present sample. (From English summary.)—E. M. Hume.

852

MARESH, M. M. **Linear growth of long bones of extremities from infancy through adolescence.** *Amer. J. Dis. Child.*, 1955, **89,** 725–742. [Child Res. Counc., Denver, Colo.]

A further report on a study of growth in length of the long bones from infancy to maturity for both sexes (see Abst. 3292, Vol. 13). Measurements of these lengths have been obtained from X-ray examinations made at regular intervals on 175 subjects. In addition to the bone lengths, height and sitting height were recorded on each occasion. This is a longitudinal study, but up to the present the records for each subject cover only a section of the total age range. Measurements are grouped at ages of 2, 4 and 6 months, and then by 6-monthly intervals from one year to 18 years, males and females being treated separately. On the average there are over 40 sets of measurements in each of the age and sex groups.

The growth of the bones of each individual has been assessed by finding at each age where they stand in relation to the rest of that age group. This is expressed numerically by the percentiles, the percentages of the comparable measurements which they exceed. Attention is thus focused on relative rather than on absolute growth, but tables are given of the lengths in cm. corresponding to the 10th, 25th, 50th, 75th and 90th percentiles for each group.

For detailed discussion the total age range is divided into 3 parts. In the period of infancy up to 3 or 4 years there are marked differences in growth from one child to another and also from one bone to another, so that there are changes in relative lengths of up to fifty percentiles. The picture is quite different for the mid-childhood period, from about 3 to 9 years in girls and about 4 to 11 years in boys. Here there are much smaller changes in percentile values, and the bones all behave in much the same way. Finally, in the adolescent period up to the completion of long-bone growth, there is again more variation, much of it associated with variations in the onset, magnitude and duration of the adolescent growth spurt.

A further analysis was made to study the relation between early adult height and childhood height, taking the latter at age 6 for girls and 7 for boys. The results showed that those who mature early tend to have a smaller adult height than those of the same childhood height who mature late.

I. McDonald.

853

ASMUSSEN, E. and HEEBØLL-NIELSEN, K. **A dimensional analysis of physical performance and growth in boys.** *J. Appl. Physiol.*, 1955, **7,** 593–603. [Lab. Theory Gymnastics, Univ. Copenhagen.]

Anatomical and physiological measurements were made on Danish schoolboys from 7 to 16 years of age. The data were split up into classes by height, and mean values of the other measurements were obtained for each height. It was found possible to express the change of each measurement with increasing body height by fitting equations of the form $y = ah^b$ to the data, where h is the height, y is the other measurement and a and b are

numerical constants differing for each measurement. The values of the exponent b found in this way, were compared with the values which would be expected if growth of schoolboys took the form of an equal proportionate increase in all the linear dimensions of the body and was unaccompanied by any qualitative change in the tissues. The differences between the observed values of b and those expected on this simple hypothesis are discussed in detail and show where the hypothesis must be modified. For the anatomical measurements the predictions were not far out, although there was a slight decrease in the ratio of trunk length to body length as height increased, which caused weight to increase at somewhat less than the expected third power of the height. There were bigger differences in the respiratory measurements, particularly in the maximum voluntary breathing capacity, which increased much less with height than would be expected, although the maximum inspiratory and expiratory forces increased more than would be expected. It is concluded that the linear dimensions of the bronchi do not increase in proportion to height. The most striking discrepancy concerned muscular strength, which was found to increase at significantly more than the expected second power of height, although by different amounts for the different groups of muscles tested. This point is discussed in detail and it is concluded that there is a qualitative increase in muscular strength due to increasing ability to mobilise and co-ordinate the muscles as the nervous system reaches maturity.—I. McDonald.

854

OSGOOD, E. E. **Development and growth of hematopoietic tissues. With a clinically practical method of growth analysis.** *Pediatrics*, 1955, **15**, 733–751. [Div. Exp. Med., Univ. Oregon Med. Sch., Portland.] Spanish summary.

From a survey of the literature tables have been compiled showing for different stages of gestation, childhood and adolescence and for adults bodyweight, height, weights of liver, spleen and thymus, blood volume, Hb and number of red cells and white cells in blood and marrow. Growth in bodyweight, organ weight, volume or number of cells is described by straight lines on logarithmic paper. The equation used to describe the straight lines is

$$y_2/y_1 = (t_2/t_1)^x,$$

where y is any measured variable and t the time from fertilisation in pre-natal life and from birth in post-natal life. Then $x = d(\log y)/d(\log t)$, *i.e.*, the slope of the straight line.

The qualitative development of the haematopoietic system in early foetal life is outlined and the total number of cells in the human foetus, at the ages of about 56 and 150 days, has been calculated from estimations of deoxyribonucleic acid phosphorus.—F. C. Aitken.

CUTHBERTSON, D. P. **Some aspects of nutrition in relation to pregnancy and lactation and to the toxaemias of pregnancy.** *Patna J. Med.*, 1955, **29**, 197–203. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

856

HOLEMANS, K. Les protéines sériques de la femme indigène du Kwango pendant la grossesse et la lactation. [**Serum proteins in native women of the Kwango during pregnancy and lactation.**] *Ann. Soc. belg. Méd. trop.*, 1955, **35**, 29–34. [Lab. Nutrit., Hôp. Feshi, Belgian Congo.] Flemish summary.

In 36 women of the Kwango at term the mean serum values for total protein and for albumin were considerably below the mean for the non-pregnant adult population of the same district. During lactation there was a steady rise in the values for total protein and albumin until, at the end of 2 years' lactation, they were about the same as for the non-pregnant women. At term the serum globulin value was slightly lower than for the non-pregnant population, but during lactation it increased to reach its highest value at the end of the first year; it then fell gradually to normal at the end of lactation. The albumin : globulin ratio was lowest at the end of the first year's lactation. The diet was extremely low in protein. The unexpected rise in the serum protein during lactation was related to the very small secretion of milk of 350 ml. a day, containing 1·1 per cent. protein, representing a daily loss of 0·61 g. N, compared with an average daily secretion in better-fed lactating women of 800 ml., representing a daily loss of 1·9 g. N, which is greater than the average N requirement during pregnancy. Eclampsia was never seen in the district, though it is not uncommon in Léopoldville, where the fall in the serum albumin during pregnancy is known to be considerably greater than in the Kwango women studied.—L. Wills.

FERRANDO, R., JACQUES, F., MABBOUX, H. and SOLLOGOUB, C. Influence du tourteau d'arachide délipidé par extraction sur la croissance et l'intégrité des testicules du rat. [**Effect of solvent-extracted groundnut cake on growth and integrity of the testicles of the rat.**] *C.R. Acad. Sci.*, 1955, **241**, 107–109.

There were 3 groups of 5 rats weighing from 85 to 89 g. The basal diet contained, in g., defatted casein 147, brewer's yeast 73, sugar 757 and salt mixture 25. In the 2 experimental groups the diet contained 8·7 per cent. extracted groundnut cake or 8·6 per cent. pressed groundnut cake at the expense of enough casein to keep the protein contents equal. All received vitamins A and E. After 344 days the rats were killed and their testes were examined.

The rats on the basal diet and those given extracted cake grew a little less than is normal, but appeared healthy. Their testicles weighed on the average only 0·8 g., compared with 2·8 in the group given pressed cake, and showed histological degeneration. It is suggested that solvent extraction of the cake had removed essential fatty acids.

D. Duncan.

858

FERRANDO, R., JACQUES, F., MABBOUX, H. and PRIEUR, G. Influence du tourteau d'arachide délipidé par extraction sur la fécondité de la femelle du rat. [**Effect of solvent-extracted groundnut cake on fertility in the female rat.**] *C.R. Acad. Sci.*, 1955, **241,** 253–254.

The experimental conditions were similar to those in the preceding Abst., but the rats were females and were allowed to breed.

The rats on the basal diet and those given solvent-extracted cake were sterile and vaginal smears showed no sign of oestrus. The 5 rats given pressed cake had 7 litters between them and a normal incidence of oestrus.—D. Duncan.

859

BAIER, W. Über den frühembryonalen Fruchttod als paternell bedingten Zuchtschaden. [**Early death of the embryo as a paternally determined genetic fault.**] *Züchtungskunde*, 1955, **27,** 93–99. [Inst. Geburtshilfe, Tierärzt. Fak., Univ. Munich.]

The evidence discussed was obtained from the literature and from the records of an artificial insemination station. It is suggested that in cows the so-called persistent corpus luteum is evidence of a previous pregnancy with early death of the embryo. A high incidence of this condition can sometimes be related to a certain bull. More study on the subject is called for.—D. Duncan.

860

BLACK, A. L., KLEIBER, M. and BAXTER, C. F. **Glucose as a precursor of amino acids in the intact dairy cow.** *Biochim. biophys. Acta*, 1955, **17,** 346–353. [Univ. California Sch. Vet. Med., Davis.] French and German summaries.

Glucose labelled with ^{14}C was injected intravenously into a lactating cow and the specific activity of the component amino-acids of casein obtained from milk taken up to 34 hr. later was studied. The percentage derived from plasma glucose was in alanine 26, serine 23, glutamic acid 10, aspartic acid 9 and glycine 7. The values for the other acids were very small. Transfer via carbonate was most frequent for the essential amino-acids, but was unimportant for the others.

A. Hepburn.

ASKONAS, B. A., CAMPBELL, P. N., GODIN, C. and WORK, T. S. **Biosynthesis of proteins. 3. Precursors in the synthesis of casein and β-lactoglobulin.** *Biochem. J.*, 1955, **61,** 105–115. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

For part 2 see Abst. 2456, Vol. 25.

The radio-activity of casein and β-lactoglobulin obtained from goat's milk after the injection of mixtures of radio-active glycine, valine and lysine was shown by partial hydrolysis to be uniformly distributed within the protein molecules. This indicated that the milk proteins were synthesised from the free amino-acids of the blood. It was suggested that any peptide formed during synthesis had only a brief existence and that exchange reactions between pre-existing protein and amino-acids were negligible.—A. Hepburn.

SENESCENCE

864

GAFFURI, E., BERRA, A. and NEIROTTI, P. G. La capacità di lavoro del torace nella vecchiaia. [**Thoracic working capacity in old age.**] *Acta gerontol.*, 1955, **5**, 67–78. [Ist. Clin. Med. Gen., Univ. Turin.] English and French summaries.

The subjects were 40 men aged from 61 to 88 years, mean 72. None had heart trouble or asthma, and slight bronchitis was ignored. A Benedict spirometer was used to record vital capacity, and maximum inspiratory and expiratory pressures were measured with an aneroid manometer. The sum of the maximum pressures expressed as fraction of atmospheric pressure and multiplied by the vital capacity in litres gave the maximum thoracic work-potential in litre-atmospheres, and this was multiplied by 24·2 to give work in g. cal. The values were compared with those for a group of 30 young men with a mean age of 30 years.

The values for the old men, expressed as percentage of those for the young, were vital capacity 57, maximum expiratory pressure 61, maximum inspiratory pressure 50, maximum work potential 32·2. The maximum work potential was $11{\cdot}6 \pm 4{\cdot}5$ g. cal., which should permit a subject of about 70 years old and 70 kg. bodyweight a maximum energy consumption during muscular work of 8 Cal. per kg. per hr. In fact the value is about 3·5 Cal. per kg. per hr., which suggests that the maximum is limited also by the efficiency of the circulation.—D. Duncan.

WATKIN, D. M., PARSONS, J. M., YIENGST, M. J. and SHOCK, N. W. **Metabolism in the aged: the effect of stanolone on the retention of nitrogen, potassium, phosphorus, and calcium and on the urinary excretion of 17-keto, 11-oxy, and 17-hydroxy steroids in eight elderly men on high and low protein diets.** *J. Gerontol.*, 1955, **10**, 268–287. [Sect. Gerontol., Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

Metabolic balance studies consisting of 12 and 13 five-day periods, respectively, with a 10-day interval between the studies, were made on 8 men aged from 70 to 93 years. During the first study daily protein intake was 106 g. and during the second 52 g. In each study the first 4 periods formed the control phase and the second 4 periods the experimental phase, when 50 mg. of the synthetic androgen stanolone were injected intramuscularly on alternate days ; the follow-up phase lasted for 4 periods in the first study and 5 periods in the second.

Stanolone caused increased retention of N, K and P, but not of Ca, on both levels of protein intake, but especially on the higher. The hormone had no significant effect on serum Ca, total protein or albumin, nor was there any effect on P or alkaline phosphatase when the protein intake was high, but with low protein intakes both P and alkaline phosphatase of plasma fell significantly when the hormone was given and approached or even exceeded control values when the hormone was withdrawn. Polymorphonuclear leucocytosis was found during the hormone treatment, but no other haematological change. Significant increases in average 17-ketosteroid excretion occurred with the hormone treatment on both protein intakes and a significant decrease occurred on cessation of treatment ; no significant change in average 11-oxysteroid or 17-hydroxysteroid excretion was found.—G. F. Garton.

EXPERIMENTAL STUDIES OF IMMUNITY AND MICRO-ORGANISMS

866

PIERCE, A. E. **Electrophoretic and immunological studies on sera from calves from birth to weaning. 1. Electrophoretic studies. 2. Electrophoretic and serological studies with special reference to the normal and induced agglutinins to *Trichomonas foetus*.** *J. Hygiene*, 1955, **53**, 247–260 ; 261–275. [Agric. Res. Counc. Inst. Animal Physiol., Babraham, Cambridge.]

1. Calves were removed from their mothers at birth and pail-fed ; some received colostrum, others had a small amount of precipitated lactoglobulin and boiled milk or glucose saline for the first 48 hr. They all received milk for from 10 to 12 weeks and hay and meal from the fourth week. Blood serum was examined in a Tiselius apparatus.

In 9 calves serum taken before they were fed contained albumin and α-, β- and γ-globulin ; in 6 the α-globulin could be separated into α_1- and α_2-components. The γ-fraction made up only 1·4 per cent. of the total protein and was considered to be either autogenous γ-globulin or globulin passively acquired *in utero*. In 4 calves given colostrum the γ-globulins rose in 24 hr. to 30·4 per

cent., albumin fell and the albumin : globulin ratio therefore fell. The α- and β-globulins were unchanged. By the next day the albumin content had begun to recover and the elimination of lactoglobulin exceeded absorption. By the tenth day after birth γ_1- and γ_2-components replaced the original lactoglobulin, and after from 60 to 80 days γ-globulin had reached 14·1 per cent., about half the adult value.

In 3 calves given precipitated lactoglobulin the passive increase was only just detectable. The α-globulins increased in the first 2 days. In one calf given whole colostrum, but not until 17 hr. after birth, the α-globulin remained constant for 2 days and then increased. All 4 showed evidence of autogenous development of γ-globulin by the tenth day, and in 3 this began within 5 days with an increase in γ_1-globulin. Changes in albumin usually occurred inversely with changes in total globulins.

The mobilities of the major components did not differ significantly from those in adult serum or change significantly in the first 6 weeks of life.

2. Colostral whey lactoglobulin contained both normal and immune agglutinins to *Trichomonas foetus*. In 4 cows the percentage of γ-globulin in serum fell in the last month of pregnancy; this may be associated with the concentration of lactoglobulin in the udder.

In calves given colostrum containing either normal or induced maternal agglutinins the elimination of passive agglutinins was logarithmic. In calves with a low titre from normal colostrum there was a gap between the disappearance of passive agglutinin and the autogenous production of normal agglutinin, but this gap was absent in calves given colostrum from immunised mothers. Autogenous normal agglutinins first appeared from 16 to 60 days after birth, whether the calves received colostrum or not. Appearance of these agglutinins was not correlated with development of any one γ-globulin. Two calves given *T. foetus* antigen developed autogenous normal agglutinins, but did not produce induced agglutinins.

D. Duncan.

BOYDEN, S. V. and ANDERSEN, M. E. **Diet in experimental tuberculosis in the guinea-pig.** *Acta pathol. microbiol. scand.*, 1955, **37**, 201–204. [Tuberculosis Immunization Res. Centre, Statens Seruminst., Copenhagen.]

The winter diet of guineapigs at the State Serum Institute consisted of hay, a concentrate mixture containing crushed oats 84, bran 30, fishmeal 1 and meat-and-bone meal 1 part, with about 100 g. fodder beet daily. In the summer diet the fodder beet was replaced by about 100 g. of equal parts of freshly cut lucerne and grass. Guineapigs were given these 2 diets at the same time and were housed in one room; 10 animals on each diet were challenged after 2 weeks with a large dose of virulent tubercle bacilli and 10 were not challenged.

The average survival time of challenged animals on the winter diet was 28 days and all were dead before the first death on the summer diet. The average survival time on the summer diet was more than 73 days. There was no death in the control groups, but animals on winter diet gained more weight than those on summer diet. No sign of nutritional deficiency was found *post mortem*.

D. Duncan.

CORRADETTI, A., TENTORI, L. and VEROLINI, F. Osservazioni sull'infezione da *Plasmodium berghei* in ratti tenuti a dieta lattea. [**Infection with *Plasmodium berghei* in rats on milk diet.**] *Rend. Ist. Super. Sanità, Rome*, 1955, **18**, 256–260. [Lab. Parassitol., Ist. Super. Sanità, Rome.] French, English and German summaries.

The rats were 2 or 3 months old and were given a stock diet or milk alone or with *p*-aminobenzoic acid for from 3 to 14 days before inoculation with one of 2 strains of *Plasmodium berghei*. In contrast to the results of other authors (*e.g.*, Abst. 4848, Vol. 23), there was no suppression of development of the parasites in rats on the milk diets. Possible reasons for the discordant results are discussed.—D. Duncan.

869

CORRADETTI, A., TOSCHI, G. and VEROLINI, F. Comportamento dei componenti proteici del siero durante l'attacco primario nei ratti infetti da *Plasmodium berghei*. [**Behaviour of serum protein components during the primary attack in rats infected with *Plasmodium berghei*.**] *Rend. Ist. Super. Sanità, Rome*, 1955, **18**, 246–255. [Lab. Parassitol., Ist. Super. Sanità, Rome.] French, English and German summaries.

The rats, in groups of 4, 6 or 8, weighed from 150 to 200 g. and were fed on the MacCollum diet with fresh liver and greenstuff. Electrophoretic studies were made on serum taken before and up to 16 days after infection with *Plasmodium berghei*.

In each group there was a small but highly significant increase in the percentage of γ-globulin 12 or 16 days after infection. In 3 out of 4 groups there was a fall in α-globulin, which in 2 groups was found on the sixth day. In one experiment there was a fall in albumin. There was no significant change in total N.—D. Duncan.

870

BERG, M. and LEVINSON, S. A. **Nephrotoxic damage by Clostridium perfringens toxin.**

Protective effect of amino acids against hyperglycemia and renal damage by C. perfringens toxin. *Arch. Pathol.*, 1955, **59**, 656–668. [Univ. Illinois Res. Hosp. Lab., Chicago.]

Nine groups of from 3 to 12 dogs were used. In 6 groups the dogs received by intramuscular injection a lethal dose of *Clostridium perfringens* toxin, 8 ml. per kg. bodyweight, and in 5 of these groups the toxin was preceded by intravenous injection of 3 per cent. *dl*-methionine solution providing 1 g. amino-acid per kg. bodyweight, or a similar dose of arginine or glycine, or 5 per cent. dextrose solution, or isotonic saline. Other groups were given the amino-acids but no toxin. Blood pressure, urine volume, urine sugar, haematocrit, blood chloride, urea N and blood sugar were studied until the dogs were killed, usually about 4 hr. after the injection of toxin. Kidney and other tissues were examined histologically.

The amino-acids when given alone produced no histological change in the kidney. The toxin alone produced high blood sugar, but no sugar in the urine. The rise in blood sugar was prevented by the amino-acids and by dextrose, but not by saline. The toxin alone destroyed alkaline phosphatase activity in the brush border of cells of the proximal convoluted tubules. This was best protected by dextrose, less well by glycine and arginine and least by methionine. The amino-acids, but not dextrose, protected the mitochondria of these cells from destruction. There was no protection, by any of the substances studied, against the lethal effects of the toxin.—D. Duncan.

Bruni, A. and Stancanelli, G. Ricerche sull' alimentazione lattea esclusiva della cavia. 4. Comportamento della flora fecale. [**On the feeding of guineapigs with a diet of milk only. 4. Behaviour of the faecal flora.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 787–788. [Ist. Igiene, Univ. Messina.]

For part 3 see Abst. 2022, Vol. 22.

According to Volpone and Buda (*Arch. ital. Med. sper.*, 1939, **4**, 769) guineapigs maintained on a diet of milk die in from 10 to 20 days, but are protected by greenstuff such as cabbage.

Cultures on several media were made from the faeces of guineapigs normally fed or given only raw, summer milk. The latter all died within 19 days. With the milk diet the number of organisms, including *Bacterium coli*, increased greatly and anaerobes appeared in large numbers. Acidophil organisms increased. No light was thrown on the significance of the changes.—E. M. Hume.

872

Marget, W. and Naber, G. Über das Wachstum von Lactobacillus bifidus in erhitzter und verdauter Frauenmilch. [**Growth of *Lactobacillus bifidus* in heated and digested human milk.**] *Monatsschr. Kinderheilk.*, 1955, **103**, 181–184. [Kinderklin., Univ. Freiburg i. Br.]

Strains of *Lactobacillus bifidus* were isolated from the stools of healthy infants and grown on a culture medium to which had been added human milk, unheated or heated for different periods to different temperatures. Of 26 strains thus tested, 12 were not affected in their growth by heating of the milk; the other 14 would not grow if the heating had lasted for more than about 10 min. at from 55° to 60° C.—A. M. Copping.

Oxford, A. E. **The bacteriology and protozoology of ruminant digestion.** *J. Sci. Food Agric.*, 1955, **6**, 413–418. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

875

Gutierrez, J. **Experiments on the culture and physiology of holotrichs from the bovine rumen.** *Biochem. J.*, 1955, **60**, 516–522. [Dept. Bacteriol. Pub. Health, State Coll. Washington, Pullman.]

Holotrich protozoa from the rumen were separated from oligotrichs by sedimentation in the presence of glucose, as described by Heald *et al.* (*Nature*, 1952, **169**, 1055). Advantage was taken of the differing sedimentation rates of holotrich species to obtain separate living suspensions of *Dasytricha ruminantium* and of *Isotricha prostoma* with *I. intestinalis*.

Both genera synthesised and stored iodine-staining polysaccharide when given glucose, fructose, sucrose, inulin or raffinose. *Dasytricha* also used to a smaller extent salicin and cellobiose. Starved *Isotricha* ingested small starch grains, given as " soluble starch ".

Manometric experiments with glucose or cellobiose as substrate showed that while *Isotricha* did not use cellobiose, with *Dasytricha* suspensions gas production from cellobiose almost equalled that from glucose. *Isotricha* produced a higher $CO_2 : H_2$ ratio from glucose than did *Dasytricha*. In flask fermentation cultures lactic, acetic and butyric

acids, with traces of an unidentified acid, were formed by both genera, but the proportion of end products differed, *Dasytricha* producing relatively more acetic and less butyric acid than *Isotricha*. Amounts of CO_2, H_2 and acid per cell per hour were calculated, and the protozoan contribution of these products within the rumen was assessed. Relatively pure suspensions of *I. prostoma* had a higher metabolic rate than a mixture of *I. prostoma* and *I. intestinalis*.

Micro-Kjeldahl estimations of N in washed, counted suspensions of the 2 genera are reported.

In culture experiments with alfalfa, ground wheat and rumen fluid medium, isotrich protozoa survived for 96 hr. In small numbers they were kept alive for 3 weeks by removing them individually to fresh medium every 24 hr. The generation time at the start of these experiments was about 48 hr.—J. C. Appleby.

MISCELLANEOUS FEEDING EXPERIMENTS

876

VAN DER RIJST, M. P. J., JANSEN, B. C. P., BEEKER, T. W. and WÖSTMANN, B. S. J. **Experiments to determine the nutritive value of the average diet consumed in the Netherlands, when fed to white rats ad libitum and under conditions of restricted consumption (70 %).** *Voeding*, 1955, **16**, 708–725. [Netherlands Inst. Nutrit., Amsterdam.]

White rats were fed to appetite for 7 generations on a diet which corresponded to the national average diet. The diet was given in dried form. Its proximate composition was protein 11·4, fat 17, water 6, crude fibre 1, ash 3·7 g. and Cal. 444 per 100 g. The stock diet with which the experimental diet was compared contained protein 20, fat 6, water 12, crude fibre 1·4, ash 2·6 g. and Cal. 373 per 100 g. The experimental diet gave slower gain of weight, lower maximum weight and shorter life than the stock diet; rats lost weight during lactation on the experimental diet and gained weight on the stock diet. Five generations were fed on the experimental diet restricted in amount to 70 per cent. of that eaten by rats fed to appetite. An extra allowance of food was given to restricted animals during lactation. Food restriction had no significant unfavourable effect; it prolonged life, especially in males, and reduced the incidence of dental caries compared with unlimited intake of the same diet.

The superior growth of rats on the stock diet is attributed to the higher quantity or quality of protein, and their longer life is thought to be due to the lower fat content of the stock diet.

Some results are presented of blood urea estimations in old animals in the 3 groups.—F. C. Aitken.

877

MORALES J., V. Suplementación de la dieta estadística nacional con carbonato de calcio. **[Supplementing the average national diet with calcium carbonate.]** *Rev. Chilena Educac. fis.*, 1955, **21**, 948–952.

In an experiment lasting 35 days with 3 groups of 6 rats 39 days old a basal ration corresponding to the average national diet of Chile was supplemented for one group with dried whole milk to raise the percentage of protein from 12·2 to 14·2 and for another group with $CaCO_3$ to supply as much Ca as the supplement of milk. The rations were equal in energy value.

Total intake of food was least on the control ration. During the first week weight increases of the 3 groups were similar, and gains per g. protein eaten were also similar. In the following weeks the supplemented groups gained almost twice as much as the control group, rats given $CaCO_3$ being slightly superior to those given milk, in both weight gain and efficiency of protein utilisation. The results seem to indicate that the national average diet was not deficient in protein, but was low in Ca. But parallel experiments in which Ca lactate was used did not indicate the same advantage from this form of Ca, and further experiments are necessary.—T. D. Bell.

878

SURE, B. **Relative nutritive values of proteins in foods and supplementary value of amino acids in pearled barley and peanut flour.** *J. Agric. Food Chem.*, 1955, **3**, 789–792. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.]

The relative nutritive values of the proteins in dried whole egg, dried non-fat milk solids prepared at low and high temperatures, rolled oats, whole rye, groundnut meal, whole barley, soya bean meal, whole wheat and sorghum were estimated in a 10-week growth experiment with rats. The gain in bodyweight per g. protein intake, *i.e.*, the protein efficiency ratio, declined in the order given above. Heating for 30 min. at 205° F. appreciably reduced the nutritive value of the milk solids.

At the 8 per cent. protein level the addition of 0·4 per cent. L-lysine alone or with 0·5 per cent. DL-threonine, or with threonine and 0·5 per cent. DL-methionine, to pearl barley produced increases of 50·0, 168·4 and 224·7 per cent. in the protein efficiency ratio and of 57·2, 135·8 and 151·1 per cent. in bodyweight. Supplements of 0·5 per cent. methionine alone or with 0·5 per cent. threonine

to groundnut flour at the 9 per cent. protein level produced corresponding increases of 44·0 and 61·5 per cent. and 44·1 and 60·6 per cent.—A. Hepburn.

879

SURE, B. **Nutritive value of proteins in buckwheat and their role as supplements to proteins in cereal grains.** *J. Agric. Food Chem.*, 1955, **3**, 793–795. [Dept. Agric. Chem., Univ. Arkansas, Fayetteville.]

Whole buckwheat or buckwheat flour given at the 8 per cent. level to rats was the best plant source of protein of high biological value, with protein efficiency ratios of 2·06 and 2·03 compared with 2·53 for dried whole egg. When part of a cereal protein diet was replaced by buckwheat, growth was considerably increased. The desirability of expanding the cultivation of buckwheat in some countries is stressed.—A. Hepburn.

880

RANDOIN, L., JOURDAN, C. and CAUSERET, J. Influence du caillage sur l'utilisation digestive et sur la valeur biologique des protides du lait. Essais de supplémentation des protides du lait, du caillé et du Camembert par la cystine. **[Effect of curdling on utilisation and biological value of milk proteins. Supplementation of the proteins of milk, curd and Camembert with cystine.]** *Lait*, 1955, **35**, 272–275. [Inst. Nat. Recherche Agronom.]

The 5 products compared were commercially pasteurised and bottled milk, curd prepared from this milk and pressed to remove 500 ml. whey from each litre, the same curd with the whey restored, and 2 samples of Camembert. Diets were prepared by the addition of starch, sucrose and salt mixture and, for the 2 cheese diets, of arachis oil and agar, so that each contained 10 per cent. protein. Five similar diets were supplemented with 0·2 per cent. cystine. Groups of 5 or 10 growing rats, from 70 to 100 g. in weight, received for 9 days a protein-free diet and then the experimental diets for 16 days. Faeces and urine were collected for the last 6 days on the former diet and the last 10 days on the latter. From N estimations the coefficient of digestibility and the biological value of the proteins were calculated.

All the curdled products had a slightly higher digestibility than milk, but their biological value was always lower. The biological value of curd with whey was higher than that of curd alone or of cheese. There was no benefit from adding cystine.—D. Duncan.

881

LILY, G., MANI, G. S., BALASUBRAMANIAN, S. C. and BASU, K. P. **Growth-promoting value of milk and some indigenous milk products.** *Indian J. Med. Res.*, 1955, **43**, 243–248. [Dairy Chem. Sect., Indian Dairy Res. Inst., Bangalore.]

Five groups, each of 5 male and 5 female littermate albino rats, one month old, were reared exclusively on cooled boiled milk, dahi, khoa, kheer and channa, respectively; all the products were obtained from cow's milk (for their composition see Abst. 212, Vol. 26). Water was provided to appetite, and a mineral supplement was given which supplied 8·04 mg. Fe, 0·6 mg. Cu and 0·6 mg. Mn daily. Food intake and bodyweights were recorded. After 12 weeks males and females belonging to the same group were mated; the number of young which survived till weaning was taken as the index of reproductive performance; the weight of the young at weaning was considered to represent the lactating capacity of the mother. The weaned young rats were maintained on the same diet as their parents for 12 weeks; then they were mated as before within the same group and their reproductive performance and lactating capacity were assessed, as were those of the third generation.

For the first generation of rats, milk was superior to dahi, khoa or channa but equal to kheer in promoting growth; channa was the least nutritious of the products. With the second and third generations dahi and milk supported similar growth and significantly better growth than did kheer, which was superior to khoa or channa. The reproductive and lactating capacity of rats on milk was uniformly good in the first 2 generations, with dahi, kheer and khoa next in value. Rats on channa were sterile even in the first generation. Kheer alone allowed reproduction in the third generation; milk, dahi and khoa did not.

G. F. Garton.

882

LILY, G., MANI, G. S., BALASUBRAMANIAN, S. C. and BASU, K. P. **Supplementary value of milk and some indigenous milk products to a poor rice diet.** *Indian J. Med. Res.*, 1955, **43**, 249–253. [Dairy Chem. Sect., Indian Dairy Res. Inst., Bangalore.]

Young rats were divided into 5 groups each of 6 males and 6 females and a sixth group of 6 males. Of the first 5 groups one received the basal diet of rice 81·4, tur dhal (*Cajanus indicus*) 5, non-leafy vegetables 8·2, leafy vegetables 2·1, NaCl 0·3 and groundnut oil 3 per cent., and the others the basal diet plus 10 ml. boiled cooled milk or the dahi, khoa or channa obtained from 10 ml. milk. The sixth group received the basal diet plus kheer obtained from 10 ml. milk. The milk or its product was given first separately and was followed by the basal diet and water to appetite. After 12 weeks when food intake and bodyweights were recorded, rats of the same group were mated;

reproductive performance and milk production were studied. The experiments were continued to the third generation (see previous Abst.).

Supplementation of the rice diet with milk or its products gave growth two or more times as rapid as that with the rice diet alone; milk and the products were almost equally effective in improving the growth rate. The supplementary effect was less noticeable in the second generation. The reproductive and lactating capacity of the females on the basal rice diet was poor and breeding could not be continued to the third generation. Milk had a uniformly good effect on all 3 generations; dahi gave good survival in the first generation, but there was a sharp decline in the second. Khoa and channa ranked next in order to milk in all 3 generations considered collectively.

G. F. Garton.

883

BALASUBRAMANIAN, S. C., LILY, G., MANI, G. S. and BASU, K. P. **Nutritive value of the proteins of milk and some indigenous milk products.** *Indian J. Med. Res.*, 1955, **43,** 255–264. [Dairy Chem. Sect., Indian Dairy Res. Inst., Bangalore.]

Six adult rats were given diets containing fat 10, protein 10, salts 4 and carbohydrates 76 per cent., with added Marmite and cod liver oil. For 7 days milk, dahi, khoa, kheer and channa, respectively, were used as sources of protein, and in one experiment the diet lacked N. N balance was studied during the last 4 days of each experiment. The biological value and digestibility coefficients of milk, dahi, khoa, kheer and channa were, respectively, 76, 66, 69, 76 and 67 and 95, 98, 90, 97 and 97.

From studies on the growth of 30 young rats given a diet of maize starch, sucrose, salts and Marmite with about 10 per cent. of protein as above, the protein efficiency ratios of milk, dahi, khoa and kheer were found to be 2·013, 2·130, 2·292 and 2·316; that of channa could not be ascertained because the rats would eat so little.

G. F. Garton.

884

VALANJU, N. N. and SOHONIE, K. **The studies in the nutritive value of Bombay fish. 1. Study of fats of different fishes.** *Indian J. Med. Res.*, 1955, **43,** 223–229. [Dept. Biochem., Inst. Sci., Bombay 1.]

Fat from 10 different varieties of fish, namely, boya (*Mugil speigleri*), bombil (*Harpodon nehereus*), ghol (*Sciaena diacanthus*), halwa (*Stromateus niger*), mandeli (*Coilia dussumieri*), mushi (*Carcharias limbatus*), pala (*Hilsa ilisha*), pomphret (*Stromateus cinereus*), toli (*Belone* sp.) and colambi (*Parapeneopsis stylifera*), was analysed for N and P. The N : P ratio was calculated; the digestiibility was estimated *in vitro* with pancreatic lipase and the nutritive value for rice moth larvae was estimated.

The N : P ratio of the fats varied from 0·9 to 4·5; 8 of the ratios were near to unity. The fats of boya, bombil, ghol and colambi were easily digested; mandeli was least digestible. The digestibility *in vitro* and the nutritive value were positively correlated. The ether extracts of boya, bombil, halwa, ghol and colambi possessed higher nutritive values than those of mushi, pala, toli, pomphret and mandeli; the fat of mandeli supported poor growth. Wheat fat and mushi muscle fat had the same biological value, but the fats of boya, bombil, halwa, colambi and ghol were superior to wheat fat. The digestibilities *in vitro* and the nutritive values of the fats were not correlated with their N : P ratios.—G. F. Garton.

885

SUR, B. K. and SUBRAHMANYAN, V. **Supplementary value of lucerne at different levels in the poor rice diet.** *Current Sci.*, 1954, **23,** 188. [Central Food Technol. Res. Inst., Mysore.]

For previous work see Abst. 774, Vol. 20.

In experiments with rats on a poor South Indian rice diet to which lucerne powder was added at levels of from 2 to 16 per cent., maximum growth was found at the 4 per cent. level and was three times as great as on the basal ration alone.

J. S. Thomson.

886

SUR, B. K. and SUBRAHMANYAN, V. **Effect of lucerne supplement to the rice diet on the body composition of growing rats.** *Current Sci.*, 1955, **24,** 15–16. [Central Food Technol. Res. Inst., Mysore.]

One group of rats were fed on a poor South Indian rice diet and another group on the same diet with a supplement of 4 per cent. lucerne leaf meal. At the end of 8 weeks the average weights of the 2 groups were 79·3 and 126·2 g. The rats were killed and body composition was estimated. The supplemented group had a higher content of body solids, chiefly as lipids. Body ash was 0·61 per cent. in the controls and 0·76 per cent. in the supplemented group.—J. S. Thomson.

887

SUBRAMANIAN, N., SUR, B. K. and SUBRAHMANYAN, V. **On the role of tamarind and chilli in the rice diet.** *Current Sci.*, 1952, **21,** 190–191. [Central Food Technol. Res. Inst., Mysore.]

When tamarind and chilli are added to foods, extra salt is always required. Rat growth experiments showed that the improved growth rate found when tamarind and chilli were added to a poor rice diet (Abst. 3863, Vol. 19) was due to the extra salt, and probably to the Ca and other mineral impurities in the crude bazaar salt used. It is suggested that attempts to improve the keeping quality of salt made from sea water by

removal of impurities may impair its nutritive value.—W. M. Deans.

888

KADKOL, S. B., SRINIVASAMURTHY, V. and SWAMINATHAN, M. **Nutritive value of the seeds of *Paspalum scrobiculatum*.** *J. Sci. Indust. Res. India* [B], 1954, **13,** 744–745. [Central Food Technol. Res. Inst., Mysore.]

The millet *Paspalum scrobiculatum* is a poor man's food in India. Rats on a poor vegetarian diet supplemented with the husked millet made much poorer growth than on a similar diet supplemented with wheat. Compared with wheat the husked millet is low in Ca, P, Fe and protein.

J. S. Thomson.

889

KADKOL, S. B. and SWAMINATHAN, M. **The nutritive value of Italian millet (*Setaria Italica*).** *Science and Culture,* 1955, **20,** 340–341. [Central Food Technol. Res. Inst., Mysore.]

Analyses of whole and husked Italian millet (*Setaria italica*) are given. The husked millet had the percentage composition: moisture 10·7, protein 12·4, ash 1·2, ether extract 2·2, fibre 0·5, carbohydrate 73·0; Ca 14·0, P 240, Fe 3·8 mg. per cent., vitamin B_1 380 μg. per 100 g. In comparison with whole wheat the husked millet was low in Ca, P and vitamin B_1.

In experiments with rats a poor vegetarian diet containing husked millet was inferior to a similar diet containing wheat and a diet of husked millet supplemented with Ca was much inferior to a diet of wheat similarly supplemented.—J. S. Thomson.

RAJU, N. V. and RAJAGOPALAN, R. **Nutritive value of heated vegetable oils.** *Nature,* 1955, **176,** 513–514. [Dept. Biochem., Indian Inst. Sci., Bangalore 3.]

Groundnut, sesame and coconut oils were heated in an open iron pan for 8 hr. at 270° C. to resemble the usual practice in India, where most of the oil consumed is heated. The oils were incorporated in the diet of rats, weighing 45 to 50 g., to provide 15 per cent. of fat. Comparable littermates received the oils unheated. Average weekly gain in weight for the controls was 11·3 g. and for the groups receiving heated oil 4·6 g. Efficiency of feed conversion was much less in the latter. The average percentage of fat in the liver was 4·6 for the controls and 7·3 in the experimental group. The livers of the latter were badly damaged, congested and not of normal colour.

When heated fats were given at a level of 30 per cent. all the rats died within a week. At a level of 15 per cent. jaundice was produced.

J. S. Thomson.

FINK, H. and SCHLIE, I. Magermilch erhält Lebernekrose-verursachende Eigenschaften beim technischen Trocknen. Ein Beitrag zur alimentären Lebernekrose der Ratte. **[Skimmed milk acquires liver-necrosis-producing properties during drying. A contribution to dietary liver necrosis in the rat.]** *Naturwissenschaften,* 1955, **42,** 446–447. [Inst. Gärungswiss., Univ. Cologne.]

With diet and procedure as described in Abst. 4002, Vol. 25, roller-dried skimmed milk produced liver necrosis and death in 16 out of 16 rats. With spray-dried skimmed milk only 5 out of 16 had necrosis and the rest survived. It is concluded that some essential amino-acids may be damaged during drying.—D. Duncan.

892

SILBERBERG, R., SILBERBERG, M. and RILEY, S. **Life span of 'yellow' mice fed enriched diets.** *Amer. J. Physiol.,* 1955, **181,** 128–130. [Snodgras Lab., Sch. Med., Washington Univ., St. Louis, Mo.]

Observations were made of the life span of 335 mice of the strain YBR/Wi, divided almost equally between grey and yellow. Groups of 117, 96 and 122, respectively, were given a control diet providing 3·5 Cal., a high-fat diet, 4·6 Cal., and a high-carbohydrate diet, 3·7 Cal. per g. The high-fat diet caused obesity and shortened by a significant amount the lives of these mice, more so of the yellow than of the grey and of the males than of the females. The high-carbohydrate diet caused obesity, but had no adverse effect on life span.

D. Harvey.

GORDON, A. S., PILIERO, S. J. and TANNENBAUM, M. **Erythropoietic activity of blood and tissues of anemic rabbits.** *Amer. J. Physiol.,* 1955, **181,** 585–588. [Dept. Biol., Grad. Sch. Arts Sci., Univ. New York.]

Boiled filtrates of plasma, peripheral blood cells and liver were prepared from 10 male rabbits on a diet of Purina rabbit checkers supplemented with fresh greens and water to appetite, which were bled 3 times weekly for 3 weeks. The extracts obtained were given to 7 groups of 6 adult female rats by subcutaneous injection of 3 ml. extract daily for 9 to 17 days. Two other groups were injected intraperitoneally daily with 1 ml. marrow filtrate and residue, respectively. The blood picture was examined usually on the sixth, tenth and eighteenth days of experiment. At the end of the experiment the rats were killed and bone marrow from femur and tibia was removed for examination.

The extracts produced small but significant increases in red cell count, Hb and haematocrit

values. Reticulocytosis occurred in the rats given the plasma and blood cell extracts. Principal effects on bone marrow included increases in the percentages of nucleated erythrocytes and immature neutrophilic granulocytes. Similarly prepared filtrates from control rabbits were without effect on the blood cell values studied. Homogenates prepared from bone marrow produced no significant effect on the erythrocyte picture of intact rats.—G. F. Garton.

MAJORI, L. and SQUERI, L. Modificazioni ematologiche nella cavia e nel ratto albino per ingestione di *Allium cepa*. [**Haematological changes in the guineapig and albino rat caused by eating *Allium cepa*.**] Studio comparativo delle modificazioni ematologiche in *Rattus norvegicus* in seguito ad ingestione di *Allium cepa* di varia provenienza. [**Comparative study of the haematological changes in *Rattus norvegicus* caused by eating *Allium cepa* from different sources.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 791–792; 792–793. [Ist. Igiene, Univ. Messina.]

Administration to rats of 6 or 18 g. per kg. bodyweight daily of raw or cooked onion grown near Messina, or of concentrated extracts, caused a decrease of about one million in the red cell count, with lymphocytosis and neutropenia.

With the same doses the effect on guineapigs was very small, but when one animal was given 54 g. per kg. bodyweight daily, there was a rapid fall in the number of red cells with death on the 23rd day (*cf.* Absts. 498, 3514, Vol. 24).

Onions grown near Milan and Modena had no greater effect in promoting anaemia in rats than those grown near Messina.—E. M. Hume.

895

WILLIAMS, R. J., PELTON, R. B. and ROGERS, L. L. **Dietary deficiencies in animals in relation to voluntary alcohol and sugar consumption.** *Quart. J. Studies Alcohol*, 1955, **16**, 234–244. [Biochem. Inst., Univ. Texas.]

Two groups of 15 young rats received for 3 periods of 28 days a purified basal diet with a high or a low vitamin supplement. In the first period a choice was offered of a 10 per cent. sucrose solution or distilled water, and in the second and third the sucrose was replaced by a 10 per cent. solution of alcohol. In the third period the vitamin supplements were changed over for the 2 groups. The reactions of the rats were highly individual, but the average intake of sugar solution in the first period, and of alcohol in the second, was greater in rats with a low vitamin intake. In the third period the alcohol intake of the 2 groups was much the same after the first few days.

The observations are discussed with reference to human craving for alcohol and to the problem of the part played in it by nutritional and genetic differences.—A. M. Copping.

896

VAN DER VEEN, H. E. and HART, P. C. Oriënterend onderzoek naar het voorkomen van strumogene stoffen in steenperen. [**Preliminary studies of the occurrence of goitrogens in pears.**] *Voeding*, 1955, **16**, 619–624. [Inst. Veeteeltk. Onderzoek T.N.O., Utrecht.] English summary.

Four groups each containing 10 cockerels were fed on a normal ration of cereal and protein feeds with minerals and a vitamin supplement. One group was given pear, another pear juice and a third pear presscake, the reason for this being that the incidence of goitre is very high in an area where the population, particularly children, eat a great many pears. Most of the pears, but not enough for the entire 20 days of experiment, came from that area. They were skinned and cored, ground or pressed and the residue was dried. The fresh pear group had 234 g. daily; the other groups 236 ml. juice or 38 g. dried residue. There was no effect on the thyroids.—I. Leitch.

897

BEAN, W. B. and PONSETI, I. V. **Dissecting aneurysm produced by diet.** *Circulation*, 1955, **12**, 185–192. [Dept. Orthopaed., Coll. Med., State Univ. Iowa, Iowa City.] Interlingua summary.

Rats were given a diet containing, per cent., sweet pea (*Lathyrus odoratus*) meal 50, maize starch 28, sucrose 6, salt mixture 4, dried yeast 10 and maize oil with halibut liver oil 2. They developed skeletal demineralisation and scoliosis, which were not prevented by supplements of casein or methionine.

In different groups from 38 to 75 per cent. of the rats died after from 12 days to 9 weeks, of dissecting aneurysm of the aorta. This was when the diets were given at 22 days old, but when the diets were not given until 51 days or later there was no aneurysm. All the aneurysms were in the thoracic aorta and there was no lesion in other vessels. The skeletal lesion and the aneurysm could, it is suggested, be results of defective formation or excessive destruction of chondroitin sulphate.

It is considered suggestive that of 20 patients whose skeletons were examined after death from dissecting aneurysm, 5 had deforming kyphoscoliosis and 2 severe pigeon breast. The possible role of defects of ground substance in dissecting aneurysm in man is discussed.—D. Duncan.

898

MUHLER, J. C. **The cariogenicity of various corn diets in the rat.** *J. Dent. Res.*, 1955, **34,** 364–367. [Indiana Univ. Sch. Dent., Bloomington.]

Six cariogenic diets were used, 5 of which contained yellow maize. The sixth was a synthetic diet with 70 per cent. sucrose and 0·2 per cent. ethylenediaminetetra-acetic acid and was for comparison with the work of Stephan *et al.* (*J. Dent. Res.*, 1952, **31,** 475) and of Zepkin (*Proc. Soc. Exp. Biol. Med.*, 1953, **82,** 80), which showed that that acid produced in rats caries comparable with that found in human subjects. Of the diets with the cereal 3 had 64 per cent. maize which differed only in degree of fineness of grinding and was described as meal, grits, and a coarser form prepared in the laboratory; the 2 others had 46 per cent. maize in the last 2 of these forms and 19·5 per cent. sucrose. About 250 rats were fed on these diets for 140 days after weaning. Data are tabulated showing the average severity of caries in all groups except the one on the synthetic diet; in it all the rats died before they were 100 days old.

Caries was worst in the group with sugar and 46 per cent. maize as grits; in the other group with the same maize content in the coarser form the incidence was less. In the 3 groups with 64 per cent. cereal the incidence was not the same; it was greatest in the grits group, where the particles were of intermediate size. Increasing the amount of grits from 46 to 64 per cent. at the expense of the sucrose did not increase the incidence of caries.—D. Harvey.

899

MCCLURE, F. J. and FOLK, J. E. **Experimental variables affecting caries production in rats fed diets containing processed foods.** *J. Dent. Res.*, 1955, **34,** 358–363. [Nat. Inst. Dent. Res., Pub. Health Serv., U.S. Dept. Health, Bethesda, Md.]

In continuation of earlier work (see Absts. 2112, Vol. 23, 958, Vol. 24), 9 experiments were made in which rats were housed and given one of 2 diets under different conditions. In experiments 1 and 4 the food was given fresh daily to 38 and 29 rats, respectively, in individual cages; in experiments 2 and 6 with 60 and 39 rats it was replenished every 3 or 4 days without removal of uneaten food and the rats were housed in pairs; in experiments 7, 8 and 9 with 30, 45 and 45 rats, respectively, duration of feeding with one diet was 30, 60 and 90 days and there were from 6 to 12 animals in a cage; in experiment 5 with 29 rats the diet had been heavily contaminated with faeces before being given. Each of these experiments began at weaning. In experiment 3, with 123 rats, the mothers were given their diet during lactation and the young which, after weaning, were in groups of from 3 to 10 in a cage, had had access to their diet at an earlier age than the rats in the other experiments.

The percentage incidence of caries in the groups in the above order was 29·0 and 37·9; 43·3 and 51·3; 76·6, 97·7 and 91·1; 75·9; 80·5. The data for distribution of caries and for its severity also are tabulated. It is concluded that systems of housing and feeding are of importance in influencing both the incidence and the severity of caries in rats.—D. Harvey.

NIZEL, A. E. and HARRIS, R. S. **Effects of ashed foodstuffs on dental decay in hamsters.** *J. Dent. Res.*, 1955, **34,** 513–515. [Tufts Dent. Sch., Boston, Mass.]

Ash prepared from diet A, with whole maize 63, whole milk powder 30, alfalfa meal 6 and NaCl 1 per cent., was added at the rate of 3 parts to a mixture of 61, 29, 6 and 1 parts of those foods to provide diet B. From the birth of their young, mothers of 24 and 17 hamsters were given diets A and B, respectively, and from weaning until 20 weeks of age the young received the same diets. At that age they were killed and their dental lesions were measured by the method of Johansen (*J. Dent. Res.*, 1953, **32,** 578).

On diet A, 4 animals had no caries and for 20 with caries the average score was 0·18; on diet B, 13 had none and for 4 the average was 0·01. It is concluded that the ash contains a substance which inhibits caries, but it is not known whether the effect is local or nutritional.—D. Harvey.

902

MORAN, T., PACE, J. and HUTCHINSON, J. B. **Toxicity trials: palatability of the diet as a factor in experiments on the rate of growth of rats.** *J. Sci. Food Agric.*, 1955, **6,** 324–329. [Res. Assoc. Brit. Flour-Millers, Cereals Res. Stat., St. Albans, Herts.]

The growth of weanling rats fed on a diet containing fat extracted from flour treated at 600 p.p.m. with NCl_3 was significantly slower than that of rats supplied with fat from untreated flour or flour treated with 300 p.p.m. of ClO_2. The slower growth was due to a smaller food intake. No pathological change was found. Other

experiments showed that fats from flour untreated, treated with ClO_2 and treated with NCl_3 were preferred in that order. The peroxide value of the fats and complete diets increased in that order. Growth rate was therefore reduced by a decrease in palatability of the diet.—A. Hepburn.

903

WASSERMAN, R. H. and TRUM, B. F. **Effect of feeding dogs the flesh of lethally irradiated cows and sheep.** *Science*, 1955, **121,** 894–896. [Univ. Tennessee–U.S. Atomic Energy Commission, Agric. Res. Programme, Oak Ridge.]

Pups fed from weaning for over 18 weeks on a diet containing flesh from cows or sheep treated with lethal doses of γ-radiation had weight gains, final weights and haematological values similar to those of pups fed on normal flesh. No pathological change was found. The results were similar in albino rats and chicks.—A. Hepburn.

904

POLING, C. E., WARNER, W. D., HUMBURG, F. R., REBER, E. F., URBAIN, W. M. and RICE, E. E. **Growth, reproduction, survival and histopathology of rats fed beef irradiated with electrons.** *Food Res.*, 1955, **20,** 193–214. [Res. Labs., Swift and Company, Chicago, Ill.]

Weanling rats in 2 groups of 80, 40 of each sex, were fed to appetite on a diet of the following percentage composition, on a dry basis: beef solids 45, maize starch 43, salt mixture 4, liver concentrate 2, Ruffex 2, vitamin A and D oil 1, wheat germ oil 1, yeast 1, orthophosphoric acid 1, with 1 mg. per cent. of 2-methylnaphthoquinone from the 11th week, intended to provide all known nutrient requirements. In one group the beef solids were supplied by ground raw beef hamburger and in the other by the same sterilised by exposure to a beam of electrons. The diets contained about 42 per cent. moisture and 12 per cent. protein. The beef hamburger supplied from 60 to 65 per cent. of the total energy. The experiment was continued for 2 years and into the third generation, 2685 rats in all. Weight and food consumption were recorded weekly. Blood of the parent generation was examined during the 11th and 15th months and after 20 months, and some animals were killed after 3, 6, 12 and 18 months for pathological examination, as were also some of the offspring. The results are tabulated.

With both diets the rate of growth was unusually good. Unexpected deaths among the offspring of rats fed on irradiated beef were probably due to muscular dystrophy resulting from marginal vitamin E intake, since they were prevented subsequently by a supplement of DL-α-tocopherol, 10 mg. per rat daily for 5 days a week. There was evidence suggesting that irradiated beef contained some oxidising substance which destroyed part of the tocopherol in the diet during mixing and storage. Apart from this, no great difference between the groups was found. There was no evidence of tumour production or ill effect on the blood picture. Slight, not always significant, inferiority of the groups given irradiated beef in growth, food efficiency, reproduction and survival was interpreted as due to slight reduction of the nutritive value of the beef hamburger, not to impairment of its protein or to a toxic effect; ordinary sterilisation by heat might have yielded similar results. Growth and food efficiency tended to improve in succeeding generations rather than to decline. It is concluded that sterilisation of beef by a beam of electrons does not significantly impair its nutritive value or wholesomeness.

905

COLE, L. J., HABERMEYER, J. G. and BOND, V. P. **Recovery from acute radiation injury in mice following administration of rat bone marrow.** *J. Nat. Cancer Inst.*, 1955, **16,** 1–9. [Div. Biol. Med. Sci., U.S. Naval Radiol. Defence Lab., Francisco, Calif.]

Groups of up to 40 adult female mice of strain LAF_1 had total body exposure to X-rays in lethal doses of 790 to 815 r. Some mice received, usually 2 to 3 hr. after exposure, 60 to 90 mg. bone marrow from rats, injected in suspension into the tail vein. Controls received phosphate buffer or sucrose and salt solution.

All the controls died within 14 days, but in different groups up to half the mice given bone marrow, and on the average one-third of them, were alive after 30 days. Such mice ceased to lose weight after about 8 days, and leucocyte counts rose from the twelfth day. Bone marrow destruction was reversed and spleen regeneration was shown by increasing content of deoxyribonucleic acid. Many late deaths occurred.

Injections of cortisone enhanced the protective effect of bone marrow.—D. Duncan.

GENERAL METABOLISM AND FEEDING HABITS OF ANIMALS OTHER THAN MAMMALS AND BIRDS

KARKHANIS, Y. D. and MAGAR, N. G. **Component fatty acids of Indian snake oils.** *Biochem. J.*, 1955, **60**, 565–568. [Dept. Biochem., Inst. Sci., Bombay 1.]

The fatty acids of the oils from the Indian python (*Python molurus*) and the Indian diamond snake (*Python stinotis*) were estimated by ester fractionation after preliminary separation by low-temperature crystallisation. The major component saturated acids in both fats were palmitic and stearic acids. Among the unsaturated fatty acids, oleic and eicosenoic acids predominated in both fats; of the minor component acids **hexadecenoic, octadecadienoic and octadecatrienoic acids** were present in both fats, but eicosatetraenoic acid was found only in the diamond snake fat and docosenoic acid only in the python fat.—G. A. Garton.

FORTUNE, P. Y. **Comparative studies of the thyroid function in teleosts of tropical and temperate habitats.** *J. Exp. Biol.*, 1955, **32**, 504–513. [Dept. Zool., Univ. Leeds.]

The species of fish were *Phoxinus laevis*, found in England in temperatures from that of ice-covered water to 23° C., and *Lebistes reticulatus*, which lives in waters at from 15° to 35° C., with an optimum of 25° C. Groups of 10 fish were kept in tap water and in solutions of 0·05 g. thiourea per 100 ml. water, *Phoxinus* at 3°, 15°, 20° and 25° C. and *Lebistes* at 20°, 25° and 30° C. *Phoxinus* controls could not survive for a week at 25° C. One fish from each group was killed twice weekly. Thyroid activity was estimated histologically and expressed as the percentage ratio of cell area to total follicular area.

In *Phoxinus* in tap water there was only slight increase in thyroid activity with increasing temperature, but in *Lebistes* thyroid activity was greater at 30° and 25° C. than at 20° C. At all temperatures in both species the activity ratio rose during exposure to thiourea, and the higher the temperature, the more quickly was the maximum attained. *Phoxinus* tolerated much higher temperatures with thiourea than without, surviving indefinitely at 33° C.

When the experiments were repeated at different times of the year, *Phoxinus* was shown to have peaks of thyroid activity in April and May and in late August and September, at all 3 temperatures, but *Lebistes* had no seasonal variation.

When *Phoxinus* eggs were hatched in thiourea solution the young developed with thyroid hyperplasia, but there was only a slight and temporary reduction of growth rate and the fish were the same size as controls 3 months after hatching. In *Lebistes* born from females kept in thiourea there was thyroid hyperplasia at birth, but no difference in growth rate.—D. Duncan.

STAMM, M. D. and AGUIRRE, L. Estudo sobre bioquímica de insectos. 1. Amino-acidos aromaticos y triptófano en la metamorfosis de *Saturnia Pyri*. [**Biochemistry of insects. 1. Aromatic amino-acids and tryptophan in the metamorphosis of *Saturnia pyri*.**] 2. Aminoácidos aromáticos y triptofano en la metamorfosis de *Pieris Brassicae* y *Ocnogyna Baetica*. [**2. Aromatic amino-acids and tryptophan in the metamorphosis of *Pieris brassicae* and *Ocnogyna baetica*.** 3. Aminoácidos aromáticos y triptófano en dos coleópteros, un hemíptero y un ortóptero. [**3. Aromatic amino-acids and tryptophan in two coleopterans, a hemipteran and an orthopteran.**] *Rev. Española Fisiol.*, 1955, **11**, 63–68; 69–73; 75–81. [Inst. Español Fisiol. Bioquim., Madrid.] English summaries.

1. Caterpillars of *Saturnia pyri* contained much phenylalanine, but the proportion of phenylalanine fell in the chrysalis and the adult moth; that of tyrosine slightly increased. In the caterpillar and the chrysalis there was more albumin than globulin, but the reverse was true of the adult. In each phase glycine, serine, valine, lysine, proline, and tryptophan were identified as well as tyrosine and phenylalanine.

2. Besides the amino-acids found in *Saturnia pyri*, the caterpillars of the cabbage white butterfly, *Pieris brassicae*, contained also histidine and the chrysalides and butterflies contained glutamic acid, as did caterpillars and chrysalides of *Ocnognya baetica*. The amounts of globulin were always less than those of albumin. In *Ocnogyna* part of the phenylalanine appears to be transformed into tyrosine at pupation.

3. The coleopterans examined were *Doryphora decemlineata* and *Colaspidema atrum*, the hemipteran was *Eurydema ornata* and the orthopteran *Acridium aegyptium*. There was no important difference in amino-acid content. The insects contained more protein, albumin and globulin than the leaves which they ate.—D. Duncan.

911

ATWAL, A. S. **Influence of temperature, photoperiod, and food on the speed of development, longevity, fecundity, and other qualities of the diamond-back moth *Plutella maculipennis* (Curtis) (Lepidoptera: Tineidae).** *Austral. J. Zool.*, 1955, **3,** 185–221. [Dept. Entomol., Waite Agric. Res. Inst., Univ. Adelaide.]

At both 18° and 25° C. caterpillars of the diamond-back cabbage moth developed more slowly and produced less silk on mature cabbage leaves than on young green and white leaves. Moths from caterpillars fed on white leaves laid more eggs than those fed on young green leaves. When mature leaves were given to larvae in the second 2 instars after tender leaves in the first 2, their fecundity was depressed, but mature leaves were less harmful when given only in the fourth instar. There was some indication that male moths reared on mature leaves were of low fertility. Food had a greater influence on growth and fecundity than had length of daylight.—D. Duncan.

912

LEMONDE, A. and BERNARD, R. Importance de la choline et de certaines substances analogues dans la nutrition des larves de *Tribolium confusum* Duval. **[Importance of choline and of certain analogous substances for the nutrition of the larvae of *Tribolium confusium*, Duval.]** *Rev. canad. Biol.*, 1955, **14,** 8–13. [Dept. Biol., Laval Univ., Quebec.] English summary.

Choline was an essential nutrient for the larvae of *Tribolium confusum*, in relatively large amounts of from 1 to 4 mg. per g. purified diet. It could not be replaced by betaine or aminoethanol. Monomethylaminoethanol and dimethylaminoethanol could replace it to some extent, but could not support optimum growth of the larvae.

913

CLEMENTS, A. N. **The sources of energy for flight in mosquitoes.** *J. Exp. Biol.*, 1955, **32,** 547–552. [Dept. Zool., Univ. Cambridge.]

In *Culex pipiens*, form *berbericus*, flown on a mill to exhaustion, there was no difference in the extent of fat in the fat bodies, but glycogen had almost disappeared. Females flown to exhaustion and then fed on glucose resumed flight, and the flight reserves of the unfed female were calculated as about equal to 0·12 mg. glucose. Females fed on blood were able to fly more than twice as far as those unfed, and the energy value of the blood meal was much more than that of its sugar content, so energy was obtained from digestion products of blood.—D. Duncan.

KERMACK, W. O., LEES, H. and WOOD, J. D. **Some non-protein constituents of the tissues of the lobster.** *Biochem. J.*, 1955, **60,** 424–428. [Dept. Biol. Chem., Univ. Aberdeen.]

The water-soluble N.P.N. of lobster muscle and hepatopancreas contained amino-acids, trimethylamine oxide, glycine betaine, volatile base and taurine. Non-protein amino-N was in the greatest quantity, 200 to 400 mg. per 100 g. wet tissue, but there was less than 10 mg. per 100 ml. in blood. Muscle contained 15 free amino-acids, hepatopancreas 7 and blood 6. Relatively large amounts of proline were in muscle, taurine in hepatopancreas and glycine in all 3 tissues. Lobster blood contained 20 mg. glucose per 100 ml.

PRATT, E. L., SNYDERMAN, S. E., CHEUNG, M. W., NORTON, P., HOLT, L. E. (Jr.), HANSEN, A. E. and PANOS, T. C. **The threonine requirement of the normal infant.** *J. Nutrition*, 1955, **56,** 231–251. [Dept. Paediat., Coll. Med., Univ. New York.]

Metabolic and clinical studies were made of 8 normal infants under 6 months of age who were given a synthetic diet providing N as a mixture of 18 essential and non-essential amino-acids, all as the natural L-isomers. The composition of the mixture was based on that of breast milk. In a preliminary study the infants gained weight normally and exhibited every sign of health although some required an intake of energy higher than average.

The minimum requirement of threonine estimated by making graded reductions of the threonine in the diet and replacing it by glycine was found to be 60 mg. per kg. bodyweight daily. Reduction of the intake below this level was associated with failure to gain weight and by impaired retention of N. There was increased loss of N but not of amino-acids in the urine. Changes were found in the pattern of amino-acid excretion, especially a reduction in the amount of threonine.

G. F. Garton.

919

SNYDERMAN, S. E., PRATT, E. L., CHEUNG, M. W., NORTON, P., HOLT, L. E. (Jr.), HANSEN, A. E. and PANOS, T. C. **The phenylalanine requirement of the normal infant.** *J. Nutrition*, 1955, **56,** 253–263. [Dept. Paediat., Coll. Med., Univ. New York.]

From studies identical with those made by Pratt *et al.* (see preceding Abst.) but on 6 normal infants aged from 1 to 9 months, the minimum phenylalanine intake compatible with normal health was found to be 90 mg. per kg. bodyweight daily. Phenylalanine deficiency was associated with failure to gain weight, impaired retention of N due to increased excretion of N in urine, and reduction of the globulin level in blood. There was an increase in excretion of free amino-acids in the urine; the pattern showed a striking decrease in phenylalanine and an increase in histidine.—G. F. Garton.

FEEDING OF INFANTS AND CHILDREN

920

ARIZTÍA, A., HOWARD, J. E., ASPILLAGA, M. and JARPA, S. **The feeding of premature infants.** *Acta paediat.*, 1954, **43,** Suppl. 100, 199–210. [Luís Calvo Mackenna's Child. Hosp., Santiago.]

The organisation and feeding routine of a 40-cot premature infant unit are described. The high mortality of 29·3 per cent. in 211 infants admitted in 7 months was due in part to the poor condition of infants at admission; all were under 2000 g. birthweight and 22·7 per cent. had some infection. The success of the feeding routine was indicated by the good growth of 65 per cent. of the survivors. The feeding routine was based on a 24-hr. fast followed by small feeds, 8 or 10 a day, of skimmed or half-skimmed breast milk, with amino-acids and carbohydrates added after the eighth or tenth day. Energy intake was kept below 70 Cal. per kg. in the first week and did not exceed 100 to 115 in the second or third week. By 3 weeks of age most of the infants were receiving 5 feeds at intervals of 4 hr.—F. C. Aitken.

921

HOLMDAHL, K. **Milk drip via an indwelling nasogastric rubber tube for feeding premature infants.** *Acta paediat.*, 1955, **44,** 330–336; Suppl. 103, 109–110. [Paediat. Clin., Child. Hosp., Gothenburg.] French, German and Spanish summaries.

The method has practical advantages over the previously used technique of indwelling tube and intermittent feeding and its success has been demonstrated in a group of 72 premature infants.

F. C. Aitken.

922

YLPPÖ, A. **Premature children—should they fast or be fed in the first days of life?** *Ann. Paediat. Fenn.*, 1954–55, **1,** 99–104. [Child. Clin., Univ. Helsinki.]

A case is argued against the modern practice of starving premature babies for the first few days of life. The author's own scheme of feeding is to give 5 per cent. glucose solution on the first, glucose solution and mother's milk on the second and mother's milk alone on the third day of life. After 2 or 3 weeks mother's milk with cow's milk and sugar added is given.—F. C. Aitken.

923

NASSO, I., VERGA, A. and POTOTSCHNIG, C. Unsere Erfahrung in der Aufzucht von Frühgeburten. [**Our experiences in the rearing of premature infants.**] *Helv. paediat. Acta*, 1955, **10,** 484–490. [Kinderklin., Univ. Milan.] French, Italian and English summaries.

In the premature baby unit established in Milan with the help of UNICEF in 1952, low-fat acidified dried milk is used when human milk is not available. With both, great stress is laid on precautions to ensure sterility. No food is given for the first 48 to 72 hr.; the smaller the infant, the longer the fasting period. Infants under 1800 g. are fed by stomach tube, the smallest and those with serious heart or respiratory disorders by indwelling polyethylene tube. Feeds are frequent, up to 12 in 24 hr. Only after the first month does the diet supply as much as 100 to 110 Cal. per kg. bodyweight daily. If oedema appears in the early days of life, salt-free skimmed milk (Pannac) is used.

Anaemia is treated with blood transfusions and more recently liver and iron preparations have been used as well.

Because of shortage of beds, infants are generally sent home when they reach 2500 g., but they are supervised up to the age of 2 years; they are considered to catch up physically on normal infants in the first years of life, except for delay in teething and walking, and to show normal psychological development. Dystrophy and florid rickets have occurred only rarely, where the parents were poor or ignorant. Efforts to rear premature infants are considered well worth while, and provision of enough premature baby units to take all premature infants in poor general condition would soon reduce infant mortality in Italy to that in other countries.—W. M. Deans.

924

PRAY, L. G., POINDEXTER, M. H. and LEBIEN, W. E. **Breast feeding: a four-and-one-half-year experience.** *J. Pediat.*, 1955, **47,** 68–72. [St. Luke's Hosp., Fargo, N. Dak.]

A survey of 3729 infants showed that 1104 or 29 per cent. were not breast fed at all. The mothers of 785 of these infants had no reason for not nursing. The percentages of infants breast fed were: for 6 months or more 18; 2 to 6 months 16; 2 weeks to 2 months 18; less than 2 weeks 19. Importance is attached to antenatal education in the value of breast feeding.—F. C. Aitken.

925

HYTTEN, F. E. and THOMSON, A. M. **Clinical and chemical studies in human lactation. 10. The maintenance of breast-feeding.** *Brit. Med. J.*, 1955, ii, 232–237. [Obstet. Med. Res. Unit (Med. Res. Counc.), Dept. Midwifery, Univ. Aberdeen.]

For Part 9 see Abst. 2550, Vol. 25.

Recently published observations on the incidence of breast feeding are reviewed and the results of a further inquiry are reported.

The data presented relate to 2404 of 2769 infants delivered in Aberdeen in 1951. At the age of 3 months 35·6 per cent. of the infants were wholly breast fed and after 6 months 24·5 per cent. were still feeding from the breast although most were receiving supplementary food. The percentage breast fed at 3 months was higher for infants delivered in a private nursing home and lower for infants delivered at home than for those delivered at the maternity hospital. The proportion of women breast feeding at the time of discharge from hospital declined with maternal age. At 3 months the incidence of breast feeding was higher among older than among younger mothers. For mothers of all age groups except those under 20 the incidence of breast feeding at 3 months was higher after second than after first pregnancies and thereafter declined with increasing parity. The incidence of breast feeding during the first week was lowest in the highest social class but at 3 months the incidence increased with rising social class. Tall women maintained breast feeding better than did small women, and women of good physique and health did better than those of fair physique, who in turn did better than those of poor physique. In the whole sample the incidence of breast feeding at 3 months decreased with increasing number of persons per room of the mother's home, but this relation did not obtain within social classes.

The results are discussed with special reference to the high energy requirement for milk production.

KIMBALL, E. R., JONES, E., LEWIS, M. E. and KOLB, E. R. **The breast milk bank as a community project.** *Pediatrics*, 1955, **16,** 264–269. [Div. Paediat., Evanston Hosp., Ill.]

The organisation of the breast milk bank is described. Comparison of equal groups of 134 premature infants born before and after establishment of the bank showed that the number fed on breast milk increased threefold after the bank was established. No significant difference in length of

stay in hospital, mortality or weight gain was noted.—F. C. Aitken.

MARTIN DU PAN, R. Le rôle du goût et de l'odorat dans l'alimentation du nourrisson. [**The part played by taste and smell in infant feeding.**] *Pédiatrie*, 1955, **10,** 169–176. [Geneva.]

Reaction to solutions of sugar and salt was investigated in 20 infants aged from 3 days to 8 weeks. Even at one week infants showed preference for sugar, and strong reactions to taste were apparent in all infants more than a few days old. Olfactory and taste reactions were studied with vegetables in infants aged from 3 to 8 months. Carrots were preferred to tomatoes, peas, haricot beans or mixed vegetables. In view of the positive findings on reaction to taste and smell in very young children, it is considered that more attention should be given to palatability in planning diets for infants.—A. M. Copping.

931

CENTERWALL, W. R. and CENTERWALL, S. A. **Thickened formulas: standardization of preparation and a new method of administration.** *J. Pediat.*, 1955, **47,** 194–197. [Dept. Paediat., Sch. Med., Coll. Med. Evangelists, Los Angeles, Calif.]

Thickened mixtures are used in the treatment of pernicious vomiting in infants. A table shows the amounts of proprietary cereals to be added to a liquid preparation with 20 Cal. per oz. and the energy value and proximate composition of the resulting feed. Two brands of rice are the preparations of choice. A special feeding bottle is described.—F. C. Aitken.

932

JOPPICH, G. Über die Bedeutung der Milchmolke für die Ernährung des Säuglings. [**Importance of whey in infant feeding.**] *Ztschr. Kinderheilk.*, 1955, **76,** 531–541. [Kinderklin., Univ. Göttingen.]

Of 117 healthy infants about 2½ months old, 48 were given a 2/5 milk based on Kleinschmidt's mixture of milk, cereals and butter (*Öst. Ztchr. Kinderheilk.*, 1949, **3,** 55) and 69 the same with whey instead of water as diluent. Full details of preparation are given.

There was a greater incidence of mild diarrhoea in the whey group, ascribed to the lactose. The attacks ceased when ordinary whey was replaced by a reconstituted dried whey preparation (from Alete G.m.b.H.) supplying protein 0·5, minerals about 0·27 and lactose from about 0·7 to 0·9 per cent. Weight gains over 6 weeks were satisfactory in both groups but significantly greater in the whey group. No difference in stomach emptying time (9 infants), fat excretion (16), or serum protein (75) was found.

N balance experiments lasting 14 days or more were made on 11 male infants aged from 2 to 10 months, of whom 6 had a mixture with whey and no casein, based on the dried whey and supplying 1·5 per cent. whey protein and 2 per cent. total protein, and 5 a mixture containing casein but no whey, based on Plasmon and supplying 1·66 per cent. protein. Three infants had both at different times. With whey N retention was good, mean 49 per cent. of the N supplied; with casein it was small or negative. Weight gains could not be related to N retention and, as might have been expected with such unnatural mixtures, were generally unsatisfactory; a few infants did well with whey alone, none with casein alone.

Tests on the breakdown of whey protein by cathepsin or a preparation of pancreatic enzymes *in vitro* showed no difference between raw or boiled whey, or whey from acidified dried milk (Elodon) or from condensed milk overheated to about 120°. When 5 infants on the whey mixture of the first experiment were given the whey raw instead of heated with the other ingredients, no effect on weight gain was found, which suggests that ordinary cooking does not affect the digestibility of whey protein; but all of 8 infants given a mixture made from dried whey of which the protein was so much altered as to be insoluble in water had digestive disorders. It is possible that

slight denaturation of the whey protein may explain the poor results with whey reported by the workers of 50 years ago.—W. M. Deans.

933

NATELSON, S., PENNIALL, R., CRAWFORD, W. L. and MUNSEY, F. A. **Noncasein protein to casein ratio of feeding formulas. Effect on blood component levels in normal infants.** *Amer. J. Dis. Child.*, 1955, **89,** 656–668. [Rockford Mem. Hosp., Ill.]

The ratio of non-casein protein to casein is roughly 7 : 3 in breast milk and 1 : 3 in cow's milk. One group of 15 infants was fed at the breast and 2 groups were given cow's milk mixtures containing 2·1 per cent. protein in which the ratios of non-casein protein to casein were 3 : 2 and 1 : 8. The groups were matched for weight and sex and the feeding experiment was from the 2nd to 32nd day of life. Blood samples were analysed at intervals and *p*H and haematocrit values were estimated. Breast milk was analysed on the 7th and 30th days after parturition. Records were kept of weight gains and of volumes of mixtures consumed.

Energy intake was less in the breast-fed than in the artificially-fed groups because the greater volume of breast milk did not entirely compensate for its lower energy value. There was no significant difference in weight gain between groups. Blood urea was highest in the high-casein group and lowest in the breast milk group. Plasma protein was highest in the low-casein group. Haematocrit declined steadily with no significant difference between groups until the 32nd day of life, when that in the breast milk group was significantly higher than in the other groups. Glucose in blood rose steadily in all groups and did not differ significantly. Minerals in blood varied with the type of feeding.—F. C. Aitken.

JADRNÍČEK, M. and MORES, A. Schnelle Realimentation bei schwerer Dyspepsie und Toxicose im Säuglingsalter. [**Rapid re-feeding of infants with severe dyspepsia and toxicosis.**] *Acta paediat.*, 1955, **44,** 293–301. [Kinderklin., Palacký-Univ., Olomouc, Czechoslovakia.] English, French and Spanish summaries.

During 1952–53, 171 infants with diarrhoea, of whom 144 had severe dyspepsia and 27 toxicosis, were treated, 120 by the rapid method. After correction of dehydration, infants over 3 months were given dried whole acid milk or 2/3 strength dried milk, and infants under 3 months or atrophic infants dried buttermilk to appetite, immediately or in some after a day or two of tea or carrot soup diet; or regular breast feeding was resumed. They worked up to full feeding on the average in 5 days ; the older slow method of re-feeding took 11 days. Most children in both groups required supplementary infusions for a day or two to maintain a positive water balance. Weight gains in the 2 groups were similar, but the rapid method reduced time of treatment on the average by 8 days and relapses were fewer. Previous correction of dehydration and control of infection are important.

SCHIFF, E. Künstliche Ernährung und Ekzemverhütung beim Säugling. [**Artificial feeding and the prevention of eczema in infants.**] *Ztschr. Kinderheilk.*, 1955, **76,** 426–434. [Child. Dept., Sydenham Hosp., New York.]

Full details are given (p. 427) of the author's scheme for infant feeding, based on 2/3 milk with 5 per cent. added sugar for the first 2 months, in 5 feeds at 4-hr. intervals. Vitamins A, D and C are given from the second week of life. After 2 months only 4 feeds are given, and between 2 and 4 months cereals (Pablum), banana pulp, orange juice, prepared carrots, liver, fruit pulp, yolk of egg and finally whole egg are introduced in succession. From 3 months infants get from 400 to 450 g. whole milk, much less than is usually advocated, but no rickets has occurred. At $3\frac{1}{2}$ months the number of meals is reduced to 3, at 7 a.m., noon and 6 p.m. This pattern continues to about 14 months. The diet supplies about 700 Cal. daily. It is claimed that the infants thrive on it, with daily gains of about 30 g. and few infections ; not a single case of eczema has occurred in 20 years.

The rest of the paper is a discussion of the etiology of eczema in infants. The possible role of allergy is not denied, but the risk of sensitisation by allergens in the food is thought to be grossly overrated, and early introduction of a mixed diet relatively low in salt and water may prevent retention of surplus water in the skin and render it more resistant to external irritation.—W. M. Deans.

936

STRÖM, J. **Medical child care in Sweden: short review of its development, importance and immediate objectives.** *Acta paediat.*, 1954, **43,** Suppl. 100, 97–108. [Child Health Div., Royal Med. Board, Sweden.]

The development of the child welfare service is described and its importance is assessed mainly in terms of declining infant mortality.—F. C. Aitken.

937

MEYER ZU HORSTE, G. Über die Bedeutung der Eier als Bestandteil der Kinderernährung. [**Importance of eggs as a constituent in the diet of children.**] *Monatsschr. Kinderheilk.*, 1955, **103,** 231–235. [Städt. Kinderklin., Dortmund.]

The use is reviewed of whole egg and of egg yolk as supplements for feeding infants from 6 months of age or earlier and as substitutes for milk in diets where milk must be avoided. Diets suggested by several authors are described in detail [no references]. Beneficial results are briefly reported from treating nutritional disturbances in 25 infants aged from 10 days to 5½ months, in the Dortmund Clinic, with egg yolk as source of animal protein.

DIETARY SURVEYS AND INDIVIDUAL STUDIES

939

GOVIL, K. K. and MITRA, D. **Comparison of nutrient values of individual diets found by calculation from food tables and by chemical analysis.** *Indian Med. Gaz.*, 1954, **89,** 476–480. [Nutrit. Lab., Provincial Hyg. Inst., Lucknow.]

The weights of food eaten in 3 days by 28 medical students were recorded. Evaluation of the individual diets in terms of protein, fat, Ca, P and Fe by calculation from food tables and by chemical analysis showed such wide differences in Ca, P and Fe that calculation of nutritive value of individual diets from food tables is thought to be of doubtful value. Differences between means obtained by the 2 methods were statistically significant for Ca, P and Fe, but the difference in Fe was considered to have no practical significance.

TRULSON, M. F. **Assessment of dietary study methods. 2. Variability of eating practices and determination of sample size and duration of dietary surveys.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 797–802. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston.]

For Part 1 see Abst. 2564, Vol. 25.

Consumption of milk and intakes of protein and vitamin A were tabulated from 7-day diet records obtained from 132 children aged 10 to 12 in one school, 120 children of the same ages in a second and 70 of the first group of children re-surveyed over a year later. Correlation coefficients for each day with every other day were calculated and means, standard deviations and coefficients of variation were listed for each day of the week. For the first survey averages of intakes for the 3 days Tuesday to Thursday and for the week were calculated. Individual records were taken at random from the groups and means and standard deviations were computed on a day-to-day basis.

Protein and milk showed approximately the same amount of day-to-day association. Vitamin A showed little or no daily correlation. Increasing the length of survey from 1 to from 3 to 7 days caused standard deviations and coefficients of variation to decrease, the reductions being greatest for vitamin A. The size of sample necessary to give a stated degree of reliability was greater for vitamin A than for protein.—F. C. Aitken.

GARRY, R. C., PASSMORE, R., WARNOCK, G. M. and DURNIN, J. V. G. A. **Studies on expenditure of energy and consumption of food by miners and clerks, Fife, Scotland, 1952.** *Med. Res. Counc. Spec. Rep. Ser.* No. 289, 1955, pp. vi + 70. H.M.S.O., London. Price 5s. net.

The studies were made in 1952. Nineteen miners and 10 clerks took part in a total of 752 measurements of energy exchange in which samples of expired air were collected in Kofranyi Michaelis respirometers. During working hours records were kept by observers of the minute-to-minute activities of the subjects; while off duty the subjects themselves recorded their activities with, as far as possible, the same degree of accuracy. During the week when these data were being collected a dietary survey was made by the weighing method.

In the mine there was some mechanisation but the long distances separating shaft and coal-face had to be covered on foot. Measurements of miners' expenditures were made at work when sitting, walking, loading, girdering and hewing and, when not at work, during lying, sitting, standing and walking each at his own pace. The time study showed that, because of breakdown of the haulage system, miners were, on the average, inactive for 38 per cent. of their time spent underground; nevertheless, their output of coal was comparable with the average for the industry.

Clerks' activities were divided between indoor office duties and outdoor work connected with weighing, labelling and dispatch of coal wagons. For both groups energy expenditure during sleep was estimated by using the method of Robertson and Reid for predicting B.M.R. (Abst. 2278, Vol. 22) and the expenditure during dressing, shaving and walking was calculated from the results in the pilot study already reported (Abst. 558, Vol. 23).

Mean values showed that during sleep with daytime dozing and while not at work the daily expenditure of energy by miners, 490 and 1420 Cal., respectively, did not differ from that by clerks, 500 and 1410 Cal.; at work daily average expenditure was 1750 Cal. for miners and 890 Cal. for clerks. Mean daily intakes of energy were 4030 Cal. and 3040 Cal. for miners and clerks, respectively. Individual intakes exceeded estimated outputs of energy for 13 miners and 7 clerks; the range of differences was from + 1320 to — 540 Cal. and the overall average excess was 370 and 240 Cal., for miners and clerks, respectively. There was no difference between the groups in the proportion of energy which they derived from protein, carbohydrate and fat.

Findings in the dietary survey were compared with allowances recommended (Abst. 1264, Vol. 20), by the British Medical Association's Committee on Nutrition for energy, protein, Ca, Fe, vitamins A and B_1, riboflavin, nicotinic acid and vitamins C and D; except for deficits of riboflavin in some, diets were generally adequate.

In the final part of the report by K. Mahadeva practice or training in the use of respiratory equipment was concluded not to influence the results. Except for that during loading, which was performed with relatively little body movement, energy expenditure for all activities was found to be linearly related to bodyweight. The relation between bodyweight and energy expenditure was highly significant; that between energy intake and bodyweight also was significant, but at a lower level.—D. Harvey.

944

Rapport van de Voedingsraad over de voeding van de Nederlandse bevolking. [**Report of the Nutrition Council on the diet of the Nederlands population.**] *Voeding*, 1955, **16**, 636–645.

The report is a preliminary one and is in 2 parts.

The first is based on National Budget Survey data and is for the first quarter of 1951. It covered 3085 families spread over the whole of the Netherlands. Conditions appeared satisfactory, average consumption agreeing with average requirements. In large families of more than 5 persons intakes of energy and protein were not always adequate. In many families amounts of Ca, riboflavin and carotene also were inadequate, a state which could be improved by greater use of milk.

The second part summarises work in 1951 and 1952 with children who were grouped according to their parents' incomes. Those in the highest of the 3 income groups were taller, heavier and in better condition clinically than were those in the other groups [no data tabulated]. The average intakes of food and nutrients for the first and third groups are given.—M. Eddison.

945

Kaayk, C. K. J. Voeding en voedingstoestand van het schoolkind ten plattelande. [**Diet and nutritional condition of the schoolchild in The Netherlands.**] *Thesis, Leyden*, 1955, pp. xv + 212. English and French summaries.

This well-documented thesis reports a detailed survey of the diet and nutritional condition of 612 schoolchildren between the ages of 7 and 9 out of a total of 7000 on the island of Ysselmonde, South Holland. The island is surrounded by rivers and linked by a tunnel with Rotterdam. For the purpose of this survey the population is divided into 3 groups, in descending order of income, and each is further subdivided as agrarian or non-agrarian in origin. In many instances findings are given separately for boys and girls. The survey was made between September 1952 and June 1953. Chapter headings are: a social-hygienic and demographic survey; absenteeism; somatometric survey; clinical tests; biochemical tests; details of diet; excretion of vitamin B_1 in the urine; dental caries and diet; conclusions.

For social hygiene the conclusion is that conditions were worst in the agrarian section of group 3. For all the agrarian families 99 per cent. of fathers and 89 per cent. of mothers had been born in rural areas; for the whole survey 88 per cent. of the parents were from the country, 12 per cent. from the town. Sleeping accommodation for children was unsatisfactory for 14·6 per cent. of those in agrarian families. Total absenteeism was 4·43 per cent., of which 15 per cent. was not due to illness; it bore no relation to income group, but in a special selection of paired children those who had more than 14 absences were taller and thinner and had significantly less Hb in comparison with children without absences. In the somatometric tests great value is attached to the skeletal age, as measured by X-ray photographs of the bones of the hand. The skeletal age of children in the highest was about six months more than that of those in the lowest income group. The clinical condition of all the children was fairly satisfactory. In group 1, 22·2, 75 and 2·8 per cent. were in excellent, good and indifferent condition; for group 3 the figures were 8·3, 55·6 and 35·4 per cent. In groups 1 and 2 none and in group 3

only 0·7 per cent. were in bad condition. No relation was found between vitamin content of the blood serum and folliculosis, cheilosis or nasolabial seborrhoea. Hb and inorganic P and vitamins A and C in blood were on the average normal. Energy intake was, in all groups, above the requirement, taken to be 2000 Cal. daily, and was highest, 2262 Cal., in the lowest income group, in which consumption of carbohydrates was highest. Group 1 had more milk, egg, cheese and orange than the others. Fat consumption was well above average requirement in all income groups. There were slight deficits of animal protein, riboflavin and carotene in the low-income group in relation to the Dutch standards (see Abst. 3390, Vol. 23). Half a litre of milk was always taken daily. Fortified margarine provided most of the vitamins required. In about 40 per cent. of the children excretion of vitamin B_1 was low; this was attributed to high consumption of refined carbohydrates. Only 10 children had no caries; the average number of carious lesions was 6·08. Goitre was found in a few regions where the I content of the water was low.

Recommendations are made for feeding children and parents are advised to pay more attention to the quality and less to the quantity of the children's diets.—M. Eddison.

946

LATSKY, J. M. **Dietary habits in Finnish Lapland. Some personal investigations.** *S. African Med. J.*, 1955, **29,** 794–796. [Union Dept. Nutrit.]

Information was obtained during a visit sponsored by two international organisations and notes are now presented. Consumption of reindeer meat is high, all parts of the animal being eaten; other flesh food is obtained from elk, bear, beaver, squirrel, hare, otter, seal, sea-birds and fish. Eggs also are eaten. Reindeer milk with 33 per cent. total solids and 7 per cent. fat and cheese made from it are common foods. Foods of vegetable origin are bread made from rye and some barley and, during the winter, potatoes. Vegetables are scarce and expensive. When available in autumn some berries are eaten.

Many infants show signs of rickets in spring; the incidence is highest in central and southern districts, inland and away from supplies of cod liver oil.

In adults signs of dietary deficiencies are almost unknown and caries is rare.—D. Harvey.

947

POTGIETER, M. and MORSE, E. H. **Food habits of children.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 794–796. [Sch. Home Econ., Univ. Connecticut, Storrs.]

Diet records covering 4 to 7 days were kept by 1242 children in school grades 5 to 8. The diets were scored for nutritive quality. Rural children had better diets than city children; the diets of girls were somewhat better than those of boys; 11-year-old children had better diets than those aged from 12 to 14 years. The foods most often lacking were green and yellow vegetables and other foods rich in ascorbic acid.—F. C. Aitken.

948

LISANSKY, E. S., GOLDER, G. and LOLLI, G. **Relationship of personality adjustment to eating and drinking patterns in a group of Italian Americans.** *Quart. J. Studies Alcohol,* 1954, **15,** 545–561. [Lab. Appl. Physiol., Yale Univ., New Haven, Conn.]

An intensive study of eating and drinking habits, social and physical status, and medical and emotional disturbances was made in 50 Italian-American subjects. There was no significant difference in eating and drinking patterns, but when the subjects were classified into those with normal personalities and those with psychological maladjustments, the latter presented significantly more signs of disease and disturbance and a greater frequency of drunkeness than the former.

A. M. Copping.

949

MANN, G. V., MUÑOZ, J. A. and SCRIMSHAW, N. S. **The serum lipoprotein and cholesterol concentrations of Central and North Americans with different dietary habits.** *Amer. J. Med.*, 1955, **19,** 25–32. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Three groups of subjects were compared: (1) Mayan Indians with agricultural mode of life in rural villages in Guatemala, (2) citizens of Guatemala City or the town of Antigua on a higher social and economic level, (3) North American business and professional subjects in U.S. cities. Diet surveys were made in (1) with daily visits and, where possible, weighing of food by dietitians; the subjects in (2) themselves kept records and data for (3) were from published findings. Examinations of blood were made for cholesterol and for the lipoprotein fractions S_f 12–20 and S_f 35–100.

For the groups, in order, the mean energy intake was 2306, 2810 and 3250 Cal. with 8, 36 and 40 per cent., respectively, of calories derived from fat. The mean for cholesterol in serum in each decade of age from 20 to 60 and for both sexes was lowest in (1), and in (1) there was little evidence of the rise with age which was characteristic of (2) and (3). Differences between groups in lipoprotein levels were variable; those in women were generally higher in (1) than in (2) and (3). Changes in

weight with advancing age were in (1) towards a decrease and in (2) and (3) towards an increase.

It is suggested from the findings in (1) that a higher level of lipoproteins may be associated with a high energy turnover and leanness and from those in (2) and (3) that a higher level of cholesterol may be a consequence of storage of energy as fat. The dissociation of cholesterol and lipoproteins in these Guatemalan subjects has prompted the study which has been begun in them of the pathology of atherosclerosis.—D. Harvey.

950

UHL, E., BORREBY, K., POROTNIKOFF, O., HJARDE, W., JENSEN, F. B. and LIECK, H. Nogle undersøgelser af grønlandske levnedsmidler og kostforhold. [**Foods and diet in Greenland.**] *Beretn. vedrørende Grønland*, 1955, No. 3, part 1, pp. 123 ; part 2 (Appendix), Tables, pp. 47. [Stat. Prakt. Sundhedsmæssige Undersøg. Vit. Lab.] English summary.

This is an account of an extensive study by a team of workers led by Uhl. Part 1 includes an account of the plan of study, a description of the country and its people and of their health ; a descriptive section on the composition of Greenland foods ; studies of plant foods and of diet habits ; an account of diet surveys in 13 families and 2 hospitals ; notes on the use of imported foods ; and there are proposals for improving the people's diet. Part 2 contains all the analytical data and details of the foods and diets.

The investigation was initiated by the Danish Grønlandskommission and a dietitian, Miss Karen Borreby, spent a year in Greenland making the field studies. She collected and sent to Copenhagen such representative samples of all common foods as, and when, shortage of food in general permitted. These were analysed at Stein's analytical laboratory and vitamins were estimated at the State vitamin laboratory. Miss Borreby also estimated vitamin C in vegetables and fruits and made diet surveys. It was the original intention that this should be preliminary to a full-scale diet and clinical survey by a team as recommended by WHO ; but experts were not available and opinion in Denmark, in agreement with the views of Thomson and Duncan (*Nutrit. Abst. Rev.*, 1954, **24,** 1), was that clinical and laboratory investigations of a population with modern technical methods give information which is not in proportion to the work or the expenditure required.

The report includes data from the literature on diet of Arctic populations.

The account of health is based on earlier published reports and the experience of doctors serving in or retired from Greenland. In the out-settlements the people are sometimes underfed when weather is bad and sealing, whaling and fishing are impossible or the catch is poor. Scurvy is sometimes seen, beriberi and pellagra not at all.

Snow blindness is common ; hemeralopia is said to occur in some districts, but not in others. Keratitis, corneal opacities, conjunctivitis and fissures at the angles of the eyelids are attributed to deficiency of vitamin A, deficiency of riboflavin and the climate. The tendency to epistaxis, haemoptysis (without tuberculosis), haematemesis and melaena is attributed by one to chronic excess of vitamin A and by another to lack of vitamin K. Rickets, according to one report, is not uncommon in infants and rachitic deformities are seen in schoolchildren, at least where there is most fog and rain. The early appearance of atherosclerosis has been affirmed and denied.

The composition of the family diets compared each with the requirement in terms of U.S. National Research Council (1948) allowances showed in 2 districts generally low intakes of Ca and riboflavin and in all districts and the hospitals of ascorbic acid. Proposals are made to reinforce imported flour with Ca, riboflavin, vitamin B_1 and Fe ; to add ascorbic acid to dried milk and to cheapen dried milk ; to give schoolchildren vitamin tablets and cheese, and to try to reduce the use of sugar.—I. Leitch.

951

SCHWARTZ, R. and DEAN, R. F. A. **An investigation of the daily intakes of food of individual boys at a boarding school in Uganda.** *Brit. J. Nutrition*, 1955, **9,** 230–244. [Med. Res. Counc. Group Res. Infantile Malnutrit., Mulago Hosp., Kampala.]

A full description is given of the foods used and of the methods and conditions of their preparation. Surveys lasted 1 week, servings were weighed and records were kept of the amounts passing through the kitchen. There were 3 periods, the first with 30 boys in which, because of financial difficulties, a restricted and somewhat unpopular diet was provided, the second with 32 boys when a more acceptable diet was re-introduced but remained restricted in quantity, and the third when this same diet was provided for 19 boys in unlimited amount. The findings were compared with those for British children (see Abst. 3602, Vol. 17).

No change in energy intake with age was found. The amount of carbohydrate was as great as for British children, that of total protein was less than the intake by a British boy of 9 years of age and that of animal protein and of fat much less. Mean values for daily energy intake were about 700 Cal. less than that of the British boy of 9 and 1500 Cal. less than for one of 15 years of age. The change to the popular diet in either limited or unlimited amount made little difference to food intake because, it would seem, of the bulky nature of the

foods. Sugar was the commonest supplement and was eaten in large amounts. For the 3 periods the ranges of percentages of calories from animal and total protein, fat and carbohydrate, respectively, were 1·9 to 3·3, 9·9 to 12·5, 12·7 to 16·2, 72·8 to 76·3 compared with 7·5, 11·9, 36·4, 51·3, respectively, for British children.

Because of leakages between kitchen and dining table, intakes were much below the amounts provided by the authorities. Signs of undernutrition were absent, but further investigations are necessary to discover the effects and value of additions to such diets of protein and fat.

952

DA COSTA, A. B. S. Três casos alimentares de trabalhadores africanos. **[Three nutritional studies among African workers.]** *An. Inst. Med. trop.*, 1954, **11**, 581–604. [Inst. Med. Trop., Lisbon.] English and French summaries.

A survey of the diets of workers in 3 places in Portuguese Africa is given as illustration of a discussion of the relative importance of calories and of certain dietary essentials. There were serious deficiencies of animal protein, animal fats and some minerals and vitamins in comparison with the U.S. National Research Council recommended allowances. The possibility of introducing new foods and food habits with a view to improving the diet and health of the labourers is considered.

GRANT, F. W. **Nutrition and health of Gold Coast children. 1. Food in four communities. 2. Care and physical status of children.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 685–693; 694–702. [St. Francis Hosp. Sch. Nursing, Evanston, Ill.]

1. The communities and the numbers of households studied in each were, a forest village 5 miles from Kumasi, 4; a coastal village 8 miles from Accra, 4; a community on the edge of the forest and close to the coastal zone, 3; in Accra, 1. The numbers of children of estimated age from under 1 to 16 years studied in these respective households were 23, 16, 12 and 9. Cultivation, use and methods of preparation of foods are described and analytical data are presented on the composition of fish and maizemeal balls and on the calcium and ascorbic acid content of some vegetable foods before and after cooking. Averages are given also for the amounts of raw edible foods provided daily per child in the households.

By calculation from the U.S. National Research Council recommended allowances estimates of requirements were made and it was found that, in general, the diets were inadequate, especially in energy but to lesser degrees in vitamins A and C and in Fe. In the Accra family with its relatively high educational standard nutrients other than Ca and riboflavin were almost adequate.

2. Mothers' diet habits during pregnancy and their attitudes towards weaning and feeding of children are fully described. Clinical findings for 23 children in the first and for 62 in the second of the communities are tabulated with data for height and weight and for Hb and red cell counts in blood. Infestation with malarial and intestinal parasites was common and signs of both undernutrition and malnutrition were frequent. Education would, it is believed, assist mothers to provide such better standards of feeding for their children as are considered possible with the foods available.

954

THOMSON, B. P. **Two studies in African nutrition. An urban and a rural community in Northern Rhodesia.** *Rhodes-Livingstone Papers* No. 24, 1954, pp. x + 57. Manchester Univ. Press. Price 8s. 6d.

Of these studies made in 1947 the urban was in the Main Location and in Chilenje, a new suburban township, at Lusaka and the rural was in 3 villages among the Lala on the Serenje plateau. The first took the form of interviews at 187 and detailed surveys of 10 households in the location, at 92 and of 13 in the township and the results are given per man-value; the second, because of exchanges and sharing of food which took place, could not be treated in the same way and findings are reported per head of the group consuming the food.

In the urban survey average income and ranges in the location were £2 19s. 4d. and from £1 5s. to £13 4s. per month, and in the township £3 19s. 11d. and from £1 9s. to £11. In most households income was below £6 per month. Information on length of residence showed that most of the families had been there for from 5 to 10 years and suggested that the urban population was becoming stabilised. All but 7 per cent. of the families grew some food for themselves in what space was available for gardening. Poultry was kept by 54 households in the location and by 27 in the township. Weekly expenditure was estimated to be 11s. 7d. for the location families and 16s. 10d. for those in the township, amounts which both agreed with the findings for the detailed surveys and supported the observation that the township was attracting the better-educated and more prosperous classes. The 2 urban groups were not comparable in composition, the proportion of children to adults being much smaller in the location, 0·59 to 1, than in the township, 1·08 to 1.

On a man-value basis the evidence was that in the urban areas average daily intakes of energy, protein, vitamin A and nicotinic acid were adequate and those of fat, vitamin B_1, riboflavin and Ca

inadequate but these averages concealed the great variations that took place from week to week between the monthly pay days. Towards the end of the month meals were often reduced from 2 to 1 a day, the consistency of cereal dishes changed and meat and bread disappeared from the menus. Changes in the economy to weekly pay days and stricter control of retail prices will be necessary before the Africans can be expected to overcome their present improvidence.

In the rural survey much information of agricultural and sociological as well as of nutritional interest was collected. The foods are described in detail and the importance of small mammals, fish and caterpillars in the diet is indicated. Average intakes of nutrients are tabulated and compared with estimated requirements. For energy in the 3 villages, respectively, intakes and estimated requirements were 1392 and 2298, 1650 and 2212, 1269 and 2268 Cal. Amounts of protein, Ca, riboflavin and ascorbic acid appeared also to be less than estimated needs. It is customary for men to take meals apart from women and children and, in practice, their diets became fairly adequate at the expense of the women and children.

In schools there is no organised supervision of feeding. Some pupils, who were at home only at week-ends and who took with them their supplies for week-days, were probably having enough food, but in quality it was poorer than the ordinary village diet. Recommendations are made for improving the system of agriculture, the quality of livestock and the nutrition of children in schools.

MCCANCE, R. A. and WIDDOWSON, E. M. **Old thoughts and new work on breads white and brown.** *Lancet*, 1955, **269**, 205–210. [Dept. Exp. Med., Med. Res. Counc., Univ. Cambridge.]

In ancient Greek and Roman times brown bread carried a social stigma, although it was not without advocates who thought it superior nutritionally. Throughout English history the social stigma became less important and the advocacy of brown bread on nutritional grounds became more so. Ultimately idealistic views on the superior value of brown bread received some support from scientific experiments and in modern times the subject of controversy shifted to the relative value of enriched white bread and brown bread. The most recent experimental work on the subject, the studies of undernourished German children given different kinds of bread (Abst. 2560, Vol. 25), failed to show any superiority of one bread over another. It would seem that both lay and scientific opinion have been wrong in laying so much emphasis on the value of high-extraction flour for all persons under all conditions.—F. C. Aitken.

958

RUSSELL, C. S. **Diet in pregnancy.** *Practitioner*, 1955, **175**, 25–30. [Dept. Obstet. Gynaecol., Univ. Sheffield.]

Evidence of the importance of good nutrition in pregnancy is briefly reviewed and a specimen diet sheet for the pregnant woman is given.

KASIUS, R. V., RANDALL, A. (IV), TOMPKINS, W. T. and WIEHL, D. G. **Maternal and newborn nutrition studies at Philadelphia Lying-in Hospital. Newborn studies. 1. Size and growth of babies of mothers receiving nutrient supplements.** *Milbank Mem. Fund Quarterly*, 1955, **33**, 230–245.

Women coming to the Clinic during the first 16 weeks of pregnancy were allotted to control and supplement groups, regard being paid to race, age and parity. There were 3 supplement groups which received vitamins or protein or both. Full-term single babies were weighed and measured for length and chest girth at birth and at 1, 2 and 3 months of age. The total number of birthweights was 1141; the numbers of other measurements were smaller.

The data obtained showed no significant beneficial effect of supplementing the maternal diet on the size and growth of infants. There were some indications that a vitamin supplement given without a protein supplement had an adverse effect.

BROŽEK, J. **Nutrition and behavior. Psychologic changes in acute starvation with hard physical work.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 703–707. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

The results are briefly reported of psychomotor and intelligence tests on 12 normal young men during a complete fast, except for water as desired, of 4½ days; for the physiological results see Absts. 4692, 4693, Vol. 24.

By the 4th day of fasting there was significant deterioration in the results of tests of speed and

co-ordination and a significant increase in body sway, but strength of grip was not affected, though muscular weakness was one of the chief subjective complaints. Intelligence was not impaired, but personality tests showed changes in the direction of neurosis. The men complained of tiredness and sleepiness, and dryness of the throat although water was allowed ; desire for food was not prominent.—W. M. Deans.

SUBRAHMANYAN, V., DESIKACHAR, H. S. R., BHATIA, D. S., SUBBA RAO, G. N. and BAINS, G. S. **Development of a new type of balanced food (tonic food). 1. Process of manufacture. 2. Studies on its nutritive value.** *Indian Food Packer*, 1953, **7**, No. 7, 9 ; 10 ; 21 ; No. 8, 9–10. [Central Food Technol. Res. Inst., Mysore.]

1. The dry ingredients of the invalid food are maize starch, casein, defatted groundnut flour, food yeast, Osborne and Mendel salt mixture, with added vitamin B_1, riboflavin, nicotinic acid, Ca pantothenate and vitamin B_6. The dry mix is made into a dough, and from this are prepared rice-sized grains, semolina or fine flour. After adjustment of moisture content to 9 per cent. the food may be stored in moisture-proof containers.

2. The food, given with 6 per cent. groundnut oil and vitamins A and D to rats, supported good growth, reproduction and lactation, which were only slightly improved by additions of small amounts of milk and green vegetable. Consumer trials with Institute staff showed that the food was palatable and acceptable. The results of feeding trials with children will be reported later.

F. C. Aitken.

962

PILLE, G. Essai d'une politique alimentaire en Afrique noire. (Aspect biologique et scientifique.) [**Sketch of a food policy for native Africa ; biological and scientific aspects.**] *Rev. Élevage Méd. vét. Pays trop.*, 1955, **8**, 217–222. [Sect. Biochim. Nutrit., Org. Recherches Aliment. Nutrit. Africaines, A.O.F.]

The plan which is outlined describes efforts to encourage food conservation by Africans and the use, in such a form as will maintain its vitamin content, of the rice crop which in recent years has come to be widely cultivated. Protein requirements could be supplied from fish flour and groundnuts, minerals from crude sea salt and calcium, in particular, from the traditional sauces containing green leaves. These aims are considered attainable both financially and practically.

LANGER, A. and HENSHAW, P. S. **The interacting effects of public health, fertility behavior and general economy on standards of living. 1. Analytical approach leading to development of a country " situation index ".** *Amer. J. Med. Sci.*, 1955, **230**, 119–127 ; 146. [Nat. Committee Maternal Health, Inc., 2 East 103rd St., New York 29.] Interlingua summary.

A " Situation index " has been calculated for 70 countries and territories. This is equal to

$$CEI/N(2^P + 2^D),$$

where C is the daily calorie intake per person $\div 1000$, E is the industrial energy consumed per person per year in tons coal equivalent, I is the income per person per year in U.S. dollars, N is the number of inhabitants per sq. km., P is the crude annual increase of population per cent., and D is the crude annual death rate per cent. The index is thought to express quantitatively the living conditions in the countries and territories from the point of view of public health and " in relation to potentialities for advancement or retrogression ".—A. M. Thomson.

966

MARSDEN, A. W. **The supply of milk and dairy products to the public.** *J. Roy. Inst. Pub. Health Hyg.*, 1955, **18**, 188–206. [Commonwealth Bur. Dairy Sci., Shinfield, near Reading.]

967

SCHULZ, T. **A ' human needs ' diet: spring 1955.** *Bull. Inst. Statistics, Oxford*, 1955, **17**, 239–240.

In March 1955, when supplies of the cheaper foods were plentiful but vegetables were dear, a " human needs " diet cost 63s., a rise of 6d. since

the previous autumn (Abst. 4066, Vol. 25). The view is expressed that " the generally high standard of living benefits the purchaser of small means, since it reduces the demand for many wholesome yet inexpensive foods ", such as the cheaper cuts of meat.—W. M. Deans.

968

PANT, P. **The National Sample Survey Number 6. Survey of Faridabad township March-April 1954.** *Sankhyā, Indian J. Statistics*, 1955, **15,** 35–190.

Because of the failure of industrial development to keep pace with the development of a new town at Faridabad, 17 miles from Delhi, unemployment became serious in the refugee population for which the town catered. In the survey 500 households, about 1 in 11 of the total, were investigated. Unemployment was found not to be associated with illiteracy and to be caused merely by absence of opportunities for employment. In the total population of 23,800, the labour force numbered 6300, of whom 530 had no work, 510 almost none and 1400 others were in need of work providing higher remuneration.

One chapter (pp. 110–117) of the report deals with consumer expenditure. In 23 households with 158 persons, in which total monthly expenditure was Rs. 5 to 10 per head, 80·6 of the expenditure was on food and 49·7 per cent. on cereals. At the other extreme in 25 households with 54 persons spending more than Rs. 61 per head, 39·0 and 7·3 per cent. of total expenditure was on food and cereals, respectively. As income rose it was expenditure on cereals that fell most steeply, while expenditure on milk, vegetables, fish and eggs increased.—D. Harvey.

969

MORNET, P. Les hématozooses animales et la carence protidique des populations humaines. **[Animal diseases due to blood-borne parasites, and lack of protein for human populations.]** *Rev. Élevage Méd. vét. Pays trop.*, 1955, **8,** 277 – 283. [Lab. Féd. Élevage " Georges Curasson ", Dakar-Hann.]

The first half of this article deals with tsetse- and tick-borne diseases of animals in Africa, the second with their effects on human nutrition. These are even more extensive than is generally supposed, since the diseases often exist in a latent unsuspected form and, apart from causing immense losses of meat and milk, reduce the work capacity of draught animals and the supply of manure. Mass destruction of ticks and prevention of trypanosome diseases by drugs and development of resistant breeds of cattle are considered the most promising lines of attack. To illustrate the lack of protein in African diets, some rough 1953 estimates are given of meat consumption, including poultry but not fish, game or insects: French West Africa 6·4, Gold Coast 2·5, Belgian Congo 0·9 kg. per head per annum, compared with over 54 kg. in France. Consumption of sea fish in French West Africa exceeds 50,000, of freshwater fish 25,000 metric tons. Production of milk and milk products is estimated at only 80,000 metric tons in French West Africa, 10,000 in the Cameroons and 50,000 in French territory in East Africa.—W. M. Deans.

DIET IN ETIOLOGY OF DISEASE

METHODS OF ASSESSING STATE OF HEALTH

970

MONNEROT-DUMAINE, M. L'indice de corpulence et son calcul chez l'adulte. **[The corpulence index and its calculation in the adult.]** *Presse méd.*, 1955, **63,** 1037–1038. [Port Said.]

The corpulence index is defined as the ratio of the actual weight to the ideal weight of the person. For the latter, modification of Broca's formula by inserting the wrist circumference as a measure of the bodily framework is suggested, leading to the simple expression $\frac{1}{2}(T - 100 + 4C)$, where T is the height and C half the sum of the circumferences of the right and left wrists in cm., for the ideal weight in kg. Persons with an actual weight between 95 and 105 per cent. of this, *i.e.*, with a corpulence index between 0·95 and 1·05, are considered normal, apart from exceptional cases, *e.g.*, athletes, who may have a high corpulence index due to muscle and not to fat. The above applies to men and women aged 30 or more; persons of 25 and 20 should weigh 1·5 and 3 kg. less. Possible applications of the corpulence index are discussed.

GENERAL STUDIES

971

LOLLI, G. **Centres for research on nutritional habits and for the prevention and correction of their deviations.** *Quart. J. Studies Alcohol.*, 1955, **16,** 393–396. [Silkworth Mem. Serv., Knickerbocker Hosp., New York.]

A short note outlines the aims and plans of the Silkworth Memorial Service for research into alcoholism and related nutritional, physiological and psychological problems.—A. M. Copping.

972

HALLMAN, N., KUNNAS, M. and VARA, P. Zur Sterblichkeit und Entwicklung der Kinder von Müttern mit überstandener Schwangerschafts-Spättoxämie. [**Mortality and development of children of mothers who have survived toxaemia of late pregnancy.**] *Ann. Paediat. Fenn.*, 1954–55, **1**, 148–165. [2. Frauenklin., Univ. Helsinki.]

A study was made of 288 children born in the Clinic in the period 1945 to 1949 to 271 mothers who had had eclamptic fits or pre-eclampsia; children of 237 healthy mothers served as controls. The children of mothers whose symptoms had lasted for some time tended to be light at birth. Thirty-five per cent. of the children were premature and 11 per cent. stillborn; those who died were all under 2500 g. Mortality was also high during the first week of life but thereafter was similar to that of Finland at the time. An incomplete follow-up of 125 of the children of affected mothers and 91 of those of healthy mothers showed that the former were not in general physically or mentally inferior.—W. M. Deans.

973

SIWE, S. **Considerations on the development of dystrophia infantum.** *Acta paediat.*, 1954, **43**, Suppl. 100, 575–578. [Paediat. Clin., Univ. Lund.]

Energy values of food and excreta were measured for 5 infants with dystrophy but without signs of disorders of the circulation or of nervous or endocrine disturbance, and in 3 control infants. On a diet supplying 110 Cal. per kg. bodyweight losses were similar in the 2 groups and increasing the intake of 1 patient to 140 Cal. per kg. did not alter the rate of loss. The disease, it is concluded, cannot be ascribed to disorder of the digestion or of the absorption of food.—D. Harvey.

974

MCQUARRIE, I., ULSTROM, R. A. and ZIEGLER, M. R. **Random notes concerning the etiological mechanisms and treatment of spontaneous hypoglycemia.** *Acta paediat.*, 1954, **43**, Suppl. 100, 481–494. [Dept. Paediat., Univ. Minnesota, Minneapolis.]

Of 43 infants with low blood sugar, other than normal newborn infants, 26 were classified as cases of idiopathic hypoglycaemia with cause undetermined. All may not have been the same, but from a more intensive study of 12 of them a single clinical entity was thought to exist; it responded to treatment with corticotropin (ACTH) and the name infantile idiopathic hypoglycaemosis is considered appropriate. The danger of brain damage from hypoglycaemia, whatever its origin, emphasises the need for early diagnosis.

HILL, K. R., BRAS, G. and CLEARKIN, K. P. **Acute toxic hypoglycaemia occurring in the vomiting sickness of Jamaica. Morbid anatomical aspects.** *West Indian Med. J.*, 1955, **4**, 91–104.

Pathological findings are described in 7 fatal cases in children and in 1 adult patient who recovered from vomiting sickness. The low level of sugar in blood was associated with fatty changes in liver and in other organs and with depletion of glycogen in liver. In 2 of the patients who had had glucose by vein but who died there was evidence that storage of glycogen had occurred to a slight extent.—D. Harvey.

976

MARTIN, F. M. **Primiparae and prematurity: an inquiry carried out by the National Birthday Trust Fund in collaboration with Local Health Authorities.** *Med. Officer*, 1954, **92**, 263–270.

From records of births in Greater London and South-East Lancashire 1097 premature first single live births with birthweight $5\frac{1}{2}$ lb. or less and 1875 non-premature controls were studied. More mothers in the premature group were found to be aged 20 or under, and more were in the lower social strata. For further analyses each case of prematurity was matched in terms of maternal age and social class with a control case; the unused controls were discarded. From the matched series there was no evidence that, within social classes, the mothers of premature babies undertook paid work during pregnancy more often, did heavier work or worked longer hours, or stopped working later in pregnancy, nor was there evidence that prematurity was associated with delayed or inferior antenatal care. An association between prematurity and low maternal stature, most marked in the middle classes, was clearly demonstrated.—A. M. Thomson.

977

SCHLESINGER, E. R. and ALLAWAY, N. C. **The combined effect of birth weight and length of gestation on neonatal mortality among single premature births.** *Pediatrics*, 1955, **15**, 698–704. [Div. Med. Serv., State of New York Dept. Health, Albany.] Spanish summary.

The analysis was based on certificates of live single births in New York State, excluding New York City, in the years 1949–51. Infant death certificates were matched with the corresponding birth certificates. The chances of neonatal survival improved with increasing birthweight and length of gestation independently. For example,

at birthweights 1001 to 1500 g., the neonatal death rate decreased from 75 per cent. at 24 to 27 weeks of gestation to 40 per cent. at 36 weeks or more; at 32 to 35 weeks of gestation, the rate fell from 79 per cent. for birthweights under 1000 g. to 4 per cent. for weights of 2501 g. or more. Similar trends were found when death rates for the first day, for the period second to sixth day and for the last 3 weeks of the neonatal period were analysed separately, the relations being clearest for first-day rates.—A. M. Thomson.

978

ZUBIRÁN, S., GÓMEZ-MONT, F. and LAGUNA, J. **Endocrine disturbances and their dietetic background in undernourished in Mexico.** *Ann. Int. Med.*, 1955, **42,** 1259–1269. [Hosp. Enfermedades Nutric., Mexico.]

The concept is advanced that utilisation of hormones by malnourished tissues is reduced. This gives rise to a concentration of hormones in the blood sufficient to inhibit the pituitary and results in decreased production of pituitary hormones. This hypothesis is based on the results, mostly published previously, of histological, clinical, endocrine and dietetic studies of 543 patients with malnutrition of long standing. The diets of the patients were poor in all respects, most notably in animal protein.

A study of endocrine changes in patients given an adequate diet for several months indicated that those due to malnutrition are reversible and that increased excretion of pituitary gonadotropins occurs as a transitory phenomenon in the recovery phase.—F. C. Aitken.

979

VAN HANDEL, E. **Atherosclerosis: overnutrition or malnutrition?** *Amer. J. Digest. Dis.*, 1955, **22,** 206–211. [St. Antoniushove Hosp., Voorburg, Netherlands.]

Atherosclerosis may be due to overnutrition from an excess of cholesterol, fat or energy, or it may be due to malnutrition. These concepts are examined briefly. In support of the deficiency theory, reference is made to experimental evidence that in animals certain dietary nutrients may prevent abnormal lipid disposition, and attention is drawn to the losses of such nutrients which occur in the preparation of certain refined western foods such as cereals and fats.—F. C. Aitken.

980

FULLERTON, H. W. **The role of diet in the pathogenesis of coronary artery disease.** *Proc. Roy. Soc. Med.*, 1955, **48,** 664–667. [Dept. Med., Univ. Aberdeen.]

Coronary thrombosis, which is usually regarded as being secondary to atheroma, has for many years been increasing in incidence in the United Kingdom, and affects professional more than labouring classes. A parallel is found in fat intake which has increased since the early part of this century and rises with income. Further evidences of a link between the incidence of coronary thrombosis and dietary fat intake are reports of a wartime reduction in mortality from circulatory diseases in Norway coincident with a greatly reduced intake of fat and the finding of Keys that there is a strong correlation between the mortality from degenerative heart disease and the percentage of calories derived from fat in national dietaries.

Results of a study of the effects of lipaemia on blood coagulability are presented. From these it is concluded that coagulability of blood is considerably increased as a result of the lipaemia which follows a fat-rich meal and that in most subjects lipaemia of such degree occurs only when the intake of fat is high.

It is suggested that high fat intake leads to intravascular fibrin formation and so to an increase in atheroma. The cessation or great reduction of blood flow in the coronary arteries during the ejection phase of ventricular systole might be expected to allow deposition on the intima of the coronary tree of preformed fibrin which could start the atheromatous process.—F. C. Aitken.

981

EPSTEIN, F. H. and BOAS, E. P. **The prevalence of manifest atherosclerosis among randomly chosen Italian and Jewish garment workers. A preliminary report.** *J. Gerontol.*, 1955, **10,** 331–337. [Res. Dept., Sidney Hillman Health Centre, New York.]

The occurrence of atherosclerosis was investigated in 506 men and 398 women aged 40 and over, who were members of a Garment Workers' Union. Of these men and women 36 and 51 per cent. were of Italian, 54 and 35 per cent. of Jewish parentage; the remainder belonged to other ethnic groups. The condition was found to be as common in women as in men; in both sexes it was more prevalent among Jews than among Italians. The effects of age and ethnic group on patterns of serum lipids are described.—G. F. Garton.

982

STUNKARD, A. J., GRACE, W. J. and WOLFF, H. G. **The night-eating syndrome. A pattern of food intake among certain obese patients.** *Amer. J. Med.*, 1955, **19,** 78–86. [Dept. Med., New York Hosp.-Cornell Med. Centre.]

Observations which included a detailed history and physical examination, routine laboratory and any special tests thought necessary were made on 23 obese women and 2 obese men. The eating pattern of each was studied and in 20 the night-

eating syndrome occurred. It was characterised by the consumption of large amounts of food during the evening and night, sleeplessness and lack of appetite in the morning with negligible intake of food at breakfast. These patients had great difficulty in losing weight and attempts to do so were accompanied by a high incidence of complications. It is suggested that the syndrome represents a type of response to stress peculiar to certain obese subjects and that it is closely related to the pathogenesis of obesity. In 38 non-obese subjects the night-eating syndrome was not present.
G. F. Garton.

JARA, A. B. Grau de tolerância para os ancilostomidae na população escolar de Vila Henrique de Carvalho. [**Degree of tolerance of ankylostome infestation in the school population of Vila Henrique de Carvalho.**] *An. Inst. Med. trop.*, 1955, **12**, 43–64. French and English summaries.

Of the 94 boys and 70 girls examined in Vila Henrique de Carvalho, Angola, all but 28 were infested with ankylostomes, a mean of 15·4 ova being found in the faeces of each infested child. The mean Hb value was 81·3 per cent. and the red cell count 4·05 million per c.mm. There was a sex difference, 85·3 per cent. of boys and 77·1 per cent. of girls being infested. There was also a racial difference; 6 of 18 white children, all the 15 of mixed race and 107 of the 131 black children were affected. Hb and red cell count were lowest in the black group, and it was concluded that the most significant cause of the anaemia was poor diet.—D. Duncan.

984

JANZ, G. J., PINTO, G. L., FRANÇA, C. S. and BARBOSA, J. C. L. Estado de nutrição e infecção por ancylostomidae. [**State of nutrition and infestation with ankylostomes.**] *An. Inst. Med. trop.*, 1955, **12**, 35–42. French and English summaries.

The faeces of 100 apparently healthy African subjects were examined for ankylostome eggs. Three groups were selected, consisting of 42 subjects probably without parasites and 55 with parasites, of whom 13 seemed to be most heavily infested. Haematological and biochemical tests gave comparable values for all 3 groups, except that in the most heavily infested group the mean serum Fe was 47·8 mg. per 100 ml., against 112·8 and 104·5 mg. in the other groups.—D. Duncan.

986

DE HAAS, J. H. **Geographical pediatrics.** *Acta paediat.*, 1954, **43**, Suppl. 100, 374–381. [Dept. Maternal and Child. Health, Netherlands Inst. Prevent. Med., Leyden.]

A general article contrasting child life in East and West, with emphasis on disorders of nutritional origin.—W. M. Deans.

987

SINGH, N. **Nutritional deficiency in children.** *Indian J. Pediat.*, 1955, **22**, 107–112. [Med. Coll., Lucknow.]

Of 46,650 children attending the hospital outpatient department in the 3 years 1952 to 1954, 5 per cent. showed *xerosis conjunctivae*, 1·5 per cent. had clinical rickets; 25 per cent. had a respiratory infection, 40 per cent. had diarrhoea and 28·5 per cent. some other disease. Of 3239 children admitted to the wards, 0·6 per cent. had rickets and 0·4 per cent. had scurvy.

The findings taken with published data on the incidence of malnutrition in schoolchildren show that although a large proportion of the child population are malnourished only a small proportion develop gross anatomical changes requiring hospital treatment.—F. C. Aitken.

988

ALLEN, K. W. **The monotonous diet of the African.** *East African Med. J.*, 1955, **32**, 95–97.

Details of the Kikuyu and Giriama diets are given. It is suggested that investigations should be made into the availability of pleasant yet nourishing African foods, which would supplement the often monotonous and ill balanced diet usually eaten, and that in industrial areas and on large estates restuarants serving such food should be available to workers.—L. Wills.

989

LAWRIE, W. **A medical survey on the Kenya coast twenty-five years ago.** *East African Med. J.*, 1955, **32**, 51–58. [East African Med. Survey.]

At the beginning of the survey more than 1000 young men were examined before 50 were found fit enough to act as porters. Ankylostomiasis proved to be the most important cause of ill health. In an attempt to eradicate it 50,000 people were treated and a random sample of 10,000 was fully investigated. Water supply, sanitation and housing were shockingly bad and the mental and physical state of the people was very poor. The staple diet was maizemeal or cassava, sometimes supplemented with rice, fish, coconuts and bananas; protein and fats were always deficient. In a random sample of 5365 people only 21 per cent. showed a satisfactory state of nutrition. The rate of ankylostomiasis was very high everywhere, even

100 per cent. in some places, and the load of worms carried too was very high. Anaemia and debility were common and severe ; ascariasis, bowel infections, eye disease, hepatic enlargement, malaria and malnutrition in children were also extremely common. Hepatic enlargement was present in 5 per cent. of an unselected group of 10,000 patients. Malaria was the great killing disease. A syndrome resembling kwashiorkor was described as common among children. There was a high incidence of tuberculosis. Syphilis and gonorrhoea were rare except among the Arabs ; yaws was common among the Africans but was never seen among the Arabs.—L. Wills.

990

JACQUOT, R. Relations entre les productions animales et l'équilibre nutritif des populations humaines. [**Relations between animal products and the nutritional balance of human populations.**] *Rev. Élevage Méd. vét. Pays trop.*, 1955, **8,** 209–216. [Lab. Biochim. Nutrit., C.N.R.S.]

The importance of protein of animal origin in the human diet is discussed. Kwashiorkor is considered as a disease of animal-protein deficiency. It is demonstrated that the disease is not common among pastoral peoples in Africa who include milk and meat in their diet. Among agricultural people it is rare where fish is available. In Africa animal husbandry must be extended to eliminate the widespread deficiency of animal protein.

T. D. Bell.

991

WENT, L. N. **Kwashiorkor.** *Doc. Med. geogr. trop.*, 1955, **7,** 139. [Dept. Pathol., Univ. Coll. W. Indies, Jamaica.]

This letter states that Dr. Cicely Williams did not say that kwashiorkor meant " red boy ". She stated (Abst. 910, Vol. 6) that " the name kwashiorkor indicates the disease the deposed baby gets when the next one is born ". Objection to the use of the name kwashiorkor because it has a wrong meaning is, therefore, without foundation.

E. M. Hume.

992

FRONTALI, G. **Lack of proteins in child nutrition.** *Acta paediat.*, 1954, **43,** Suppl. 100, 318–323. [Clin. Paediat., Univ. Rome.]

Experience gained in 9 years of study of the syndrome known variously as kwashiorkor, starchy food dystrophy, or, as it is here called, hypoproteinosis, has enabled the author to separate the essential signs, which disappear after administration of animal protein, from associated signs produced by infection or vitamin deficiency. The importance of essential amino-acids is discussed and treatment by transfusion of plasma and administration of protein hydrolysate or soluble caseinate is described.—F. C. Aitken.

993

GÓMEZ, F., GALVÁN, R. R., CRAVIOTO, J. and FRENK, S. **Malnutrition and kwashiorkor.** *Acta paediat.*, 1954, **43,** Suppl. 100, 336–357. [Dept. Nutrit., Hosp. Infantil, Mexico.]

A comparison of the clinical, biochemical and histopathological pictures of malnutrition in children in Mexico and kwashiorkor in Africa leads to the conclusion that the two names refer to the same disorder. On etymological grounds the term malnutrition is preferred.—F. C. Aitken.

994

TOVAR-ESCOBAR, G. and DE MAJO, B. L. **Multiple deficiency syndromes in infants and children (Venezuelan kwashiorkor).** *Doc. Med. geogr. trop.*, 1955, **7,** 116–129. [Inst. Invest. Pediat., Caracas, Venezuela.] Spanish summary.

The syndrome has been described from many parts of Latin America ; it was found to be widespread in Venezuela among slum dwellers and in impoverished rural districts. Physical and laboratory examinations showed a picture which closely resembled that of kwashiorkor as seen in Africa; the chief difference was the absence of obvious depigmentation of the skin in most of the Venezuelan patients who, owing to their mixed racial origin, are much fairer than the average African. The diet of most of the population consists of bulky carbohydrate foods with very little animal protein, fruit or vegetables ; very little milk is available. No direct relation could be established between infestation with tropical parasites and the syndrome. The condition is considered to be a public health problem which can be dealt with only by improving the socio-economic status of the population.—L. Wills.

995

RAMANATHAN, M. K., VENKATACHALAM, P. S., SRIKANTIA, S. G. and GOPALAN, C. **A follow-up study of hundred cases of nutritional oedema syndrome (kwashiorkor).** *Indian J. Med. Res.*, 1955, **43,** 285–290. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor.]

From records of an earlier study (see Abst. 4088, Vol. 25) 100 children were chosen for re-examination. Of them 20 were not traced, 40 had had no relapse, 11 had had recurrence on one or more occasions and 29 had died. The intervals between the examinations were from 6 months to between 4 and 5 years. Living conditions, diet and economic status were studied. Dire poverty had caused living conditions to remain primitive and insanitary and had prevented improvement of the children's diets, average intakes of energy and

protein being about 105 Cal. and 2·2 g. per kg. bodyweight on both occasions. The good feeding which they received during their stay in hospital seemed to have had lasting effects on some of these children.—D. Harvey.

996

VARKKI, C., VENKATACHALAM, P. S., SRIKANTIA, S. G. and GOPALAN, C. **Study of birth weights of infants in relation to the incidence of nutritional oedema syndrome (kwashiorkor).** *Indian J. Med. Res.*, 1955, **43**, 291–296. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor.]

Records of birthweight were collected for infants born to mothers, 500 in the poorest and 200 in the well-to-do section of the community; of 207 children admitted to hospital with nutritional oedema the hospital records provided the birthweight of 34; a dietary survey with some clinical observations was made of 43 pregnant women in the poorest class. In comparison with the poor mothers' infants the distribution curve of birthweights of infants of well-to-do mothers shows a definite move to the right; the percentages of weights below 5½ lb. were 12·3 and 38·4 in the well-to-do and the poor. The average for infants later developing nutritional oedema was 6·0 lb. and did not differ from that for others of the same socio-economic class. There was no correlation between their birthweight and the age at which the disease appeared. Their mothers' values for Hb, plasma proteins and albumin were typical of poor-class women.

From these 3 lines of study it is concluded that the nutritional status of the mother will affect the birthweight of her infant but will not predispose it to develop nutritional oedema.—D. Harvey.

997

OOMEN, H. A. P. C. **The external pattern of malnutrition in Djakarta toddlers.** *Doc. Med. geogr. trop.*, 1955, **7**, 1–9. [Inst. Nutrit., Djakarta.]

The cause of the malnutrition seen was taken to be insufficiency of protein, energy and vitamin A. The syndrome had the characteristics of kwashiorkor, but the pattern varied. The patients were aged from 1 to 6 years and were typical of the children in the larger towns of Indonesia and possibly of all South-east Asia. The staple food was rice. The condition is common and the 124 children studied were seen in 10 weeks. A detailed external examination was made of each, and further tests of a limited number. The signs noted were those described for kwashiorkor but, in addition, xerophthalmia was present in 66 per cent. and keratomalacia in 41 per cent. Ten signs, subnormal weight, enlargement of the liver, subnormal height, emaciation, oedema, depigmentation of the hair and skin, cutaneous xeratrophy, crazy-pavement dermatosis, xerophthalmia and keratomalacia, and muscular wasting were combined into an index to determine roughly the degree of malnutrition. With the index it was possible to make a reasonable prognosis and to direct treatment. Analysis of the findings showed that the highest incidence of the condition was in the second and third year, that the average index for the different age groups varied only between 11 and 13, that weight deficiency decreased with age, and that the wasting of fatty tissue and liver enlargement were greatest in the youngest children. The incidence of xerophthalmia rose to a maximum in the first half of the third year and was least a year earlier. Xerophthalmia was not considered as part of the kwashiorkor syndrome, and there appeared to be no relation between it and any of the other signs. The diets of those with and without xerophthalmia showed no obvious difference; neither of them contained vitamin A, but both contained some carotene. The degree of liver enlargement varied directly with the malnutrition index in untreated patients but not in those that had been treated; the largest livers occurred in the youngest children. All the livers examined histologically showed definite steatosis, which was more marked in the larger livers.

L. Wills.

998

BROCK, J. F., HANSEN, J. D. L., HOWE, E. E., PRETORIUS, P. J., DAVEL, J. G. A. and HENDRICKSE, R. G. **Kwashiorkor and protein malnutrition. A dietary therapeutic trial.** *Lancet*, 1955, **269**, 355–360. [Dept. Med., Univ. Cape Town.]

Children numbering 135, aged between 8 and 55 months and drawn from 3 centres, Cape Town, Pretoria and Durban, were, in an attempt to discover the constituent of skimmed milk which initiates the cure of kwashiorkor, given one of 4 mixtures. These and the numbers of patients receiving them were (1) dried skimmed milk with vitamins, 28; (2) dried skimmed milk only, 33; (3) vitamin-free casein, minerals, glucose and vitamins, 44; (4) as in (3) without vitamins, 30. Initiation of cure is described in terms of disappearance of mental apathy, weight change with loss of oedema, rise in level of albumin in blood serum, improvement of skin condition and formation of new tissue as shown by gain of weight. The last is attained in the third week, and treatment was not continued beyond 24 days. The results are presented as an arrangement of the patients in 4 groups with numbers as follows, (1) those with none other than the prescribed feeding, 72; (2) those for whom treatment with antibiotics also was necessary, 8; (3) those for whom supportive

treatment with transfusions or a change of treatment became necessary, 28: and (4) those who died, 27.

The findings were that all 4 mixtures initiated recovery and that treatment 4 was no less effective than was treatment 2. It is concluded that deficiencies of known vitamins are not of major importance in the pathogenesis of kwashiorkor and that the nutrient in skimmed milk which is curative is provided by the casein, mineral and trace substances such as factor 3 (see Abst. 1037, Vol. 22).

In an addendum the results are reported of the treatment of 9 more patients with a mixture containing 18 amino-acids, glucose, minerals and vitamins. Recoveries in this admittedly small series were such as to support the view that cure is initiated by the casein in skimmed milk.

999

EALES, L., BRONTE-STEWART, B. and BROCK, J. F. **Nutritional oedema in the non-European in Cape Town.** *S. African J. Lab. Clin. Med.*, 1955, **1,** 1–21. [Dept. Med., Univ. Cape Town.]

Nineteen patients with nutritional oedema were treated with only rest in bed and, later, supplements were added to their customary diet. In order the supplements given were vitamin B_1, ascorbic acid and milk protein and finally a full diet was given. Data on bodyweight, degree of oedema, heart size, venous pressure, blood pressure, renal function, electrolyte excretion and plasma protein were recorded. The findings in 4 representative male Bantu are presented graphically, with the case histories. In 2 oedema disappeared with rest alone. In the third a similar response to rest was apparently accelerated by vitamin B_1. The fourth was a case of intractable congestive heart failure and proved fatal.

The pathogenesis of the oedema is discussed.

KÜHN, H. A. and STEIM, H. Hunger und Leberschaden. [**Starvation and liver damage.**] *Deutsch. med. Wochenschr.*, 1955, **80,** 1042–1043. [Med. Univ. Klin., Freiburg i Br.]

From clinical and biopsy studies on a 51-year-old labourer with signs of liver disorder after a diet extremely low in protein it is concluded that cirrhotic changes may occur earlier than has been supposed.—W. M. Deans.

1001

BRÜGEL, H. and PIETZONKA, H. Mangelernährung und Eisenablagerung in der Leber. [**Deficient diet and deposition of iron in the liver.**] *Deutsch. med. Wochenschr.*, 1955, **80,** 1002–1005. [Inn. Abt., Städt. Krankenhaus Stuttgart, Bad Cannstatt.]

Of over 700 patients with liver disorders subjected to laparoscopy between 1949 and 1954, 168 were known not to have been undernourished and 73 had been prisoners of war with a history of "wet" or "dry" alimentary dystrophy or were civilians showing a weight loss of over 20 per cent. From these 241 subjects frozen sections of liver tissue preserved in formalin, or paraffin wax sections of liver tissue preserved in alcohol, were examined for deposits of Fe, detected by the Turnbull's blue reaction. There were 4 categories: no Fe deposits or only traces, slight, medium and heavy.

A significant relation between undernutrition and presence of Fe deposits was found; the connection between undernutrition and degree of Fe deposition was less close but still significant at the 0·3 per cent. level. Of the 73 who had been undernourished, 34 were abusers of alcohol, but no significant connection between this habit and Fe deposits was found.

The clinical significance of Fe deposits in the liver is not clear. The authors do not express an opinion whether the liver disorder or the deposition of Fe comes first, or whether deposition of Fe can lead to cirrhosis.—W. M. Deans.

1002

BRAS, G., BROOKS, S. E. H. and DEPASS, E. E. **Data about malignant neoplasms and about the incidence of cirrhosis of the liver in Jamaica.** *Doc. Med. geogr. trop.*, 1955, **7,** 146–153. [Dept. Pathol., Univ. Coll. W. Indies, Jamaica.]

In the 2 years from 1952 to 1954, 372 autopsies were performed in the hospital; a malignant neoplasm was found in 56, but only 1 each of primary liver cell carcinoma and cholangiocarcinoma. Cirrhosis of the liver was present in 3·2 per cent., a proportion the same as was reported among 1632 autopsies at another hospital, and considerably lower than that found in other tropical countries. Comparison with the figures of the Registrar General in Spanish Town showed good agreement. Thus, though hepato-cellular carcinoma, usually arising in a cirrhotic liver, is frequent in countries where malnutrition associated with such diseases as kwashiorkor is found, in Jamaica, where such malnutrition also occurs, primary liver cell carcinoma and cirrhosis of the liver are rare. Toxic conditions, in addition to dietary deficiency, may be important in the production of cirrhosis and carcinoma of the liver; it is considered possible that the absence from the population of such complications as endemic malaria or severe helminthic infestation may account for the low incidence of these liver conditions.—L. Wills.

1003

STUART, K. L. and BRAS, G. **Clinical observations on veno-occlusive disease of the liver in Jamaican adults.** *Brit. Med. J.*, 1955, ii, 348–352. [Dept. Med., Univ. Coll. W. Indies.]

Clinical findings and the results of liver function and biopsy tests and of blood analyses are given for 4 patients, of whom 2 died. The general conclusion is that deficiency of protein has existed in the patient's diet and that " bush teas " have often been consumed. While many patients improve rapidly on a diet rich in protein and containing added vitamins, so little is known about the disease that it becomes difficult to assess accurately the value of any therapeutic treatment.

D. Harvey.

FAWDRY, A. L. **Syndrome of splenomegaly, anaemia, and hepatomegaly often left-lobed, in South Arabia.** *Trans. Roy. Soc. Trop. Med. Hyg.*, 1955, **49**, 387–398.

Clinical observations and some laboratory investigations are summarised for patients who have been living in the more inaccessible parts of Southern Yemen and the Western Aden Protectorate. The syndrome is ill defined and the splenomegaly is generally the sign which causes the patient to seek medical or surgical aid. Diet, based on *Sorghum vulgare* and *Pennisetum typhoideum* with little milk and no other animal food, has generally been very poor in quality. Enlargement of the spleen is almost certainly the result of chronic malaria. This syndrome of which these conditions appear to be the cause is thought to resemble the splenomegaly of unknown origin which has been reported from elsewhere.

1005

SCHROEDER, H. and FUCHS, M. Antibiotica und Vitaminstoffwechsel. [**Antibiotics and vitamin metabolism.**] *Klin. Wochenschr.*, 1955, **33**, 278 – 282. [Innere Abt., Luisenhosp., Aachen.]

Vitamins A, B_1 and C and nicotinic acid were estimated in the blood, and riboflavin, vitamin B_1 and nicotinic acid in the urine of 60 patients and healthy people before and after treatment with 1 of 6 antibiotics. Specimen cases are described including some in whom signs of deficiency occurred, especially the Plummer Vinson syndrome, ascribed to lack of riboflavin. Nicotinamide was found most often to fall in the blood and urine ; in the urine riboflavin fell more rapidly than the other vitamins. In the blood, vitamin A fell in a few instances but carotene increased. Vitamin C fell.

1006

BEYER S., V. Vitaminas en la dieta media estadistica nacional. [**Vitamins in the average national diet.**] *Rev. chilena Educ. fis.*, 1954, **21**, 854–856. [Dept. Aliment. Educ., Univ. Chile.]

A diet based on the average Chilean national diet was given to young rats with and without additions of the vitamin B complex and fat-soluble vitamins. There was no significant difference in weight gain between the groups. It was concluded from the experiments that social groups consuming average diets or diets above the average were unlikely to obtain any benefit from additional vitamins. Those below the average level might require some extra vitamins.—A. M. Copping.

1007

KOHN, L. A. and NICHOLS, E. B. **Interference with uptake of radioiodine tracer during the administration of vitamin-mineral mixtures.** *New Engl. J. Med.*, 1955, **253**, 286–287. [Div. Radiation Therap., Dept. Radiol., Sch. Med. Dent., Univ. Rochester, N.Y.]

The amount of radiation was measured over the thyroid gland in 8 subjects after administration of 60 μC. ^{131}I before, during and after from 5 to 9 days of a daily dose of a mineral and vitamin preparation containing 1·0 mg. I. In 3 subjects the preparation blocked the uptake of radio-active I, which recovered when the preparation was discontinued ; in 2 subjects the uptake was slightly reduced, and in 1 it was slightly increased, while the preparation was being taken. One subject had a sharp fall in uptake and was suspected of hyperthyroidism. In the remaining subject the uptake of radio-activity was apparently blocked before the test started. It is concluded that such mineral-vitamin preparations may interfere with the diagnostic use of radio-active iodine.

SCHNEIDER, J. A. and SANKOWSKY, G. Über die Behandlung von Altersheiminsassen mit Vitaminkombinationen (Protovit). [**Treatment of the inhabitants of old people's homes with mixed vitamins.**] *Münch. med. Wochenschr.*, 1955, **97**, 770–772. [Inn. Abt., Humboldt Krankenhaus, Berlin-Reinickendorf.]

In a trial with mixed vitamin treatment which lasted 6 weeks, the results of standard tests showed a statistically significant increase in physical and mental efficiency, and a general physical improvement, in 53 treated subjects compared with 20 untreated. After an interval without treatment, it was renewed and produced an even more pronounced improvement. It is suggested that the deficiency demonstrated by the treatment arose from faulty gastro-intestinal function.—L. Wills.

KAPLAN, L., LANDES, J. H. and PINCUS, J. **The nutritional status of noninstitutionalized aged**

persons. *Geriatrics*, 1955, **10**, 287 – 290. [Lower East Side Health Centre, New York City Dept. Health.]

A 24-hr. history from memory of food intake was obtained from 53 persons aged over 60 years. They were examined clinically and the blood of 49 of them was analysed for vitamin A, carotene, ascorbic acid, Fe and protein. More than half of them had vitamin intakes inadequate according to the standards of the National Research Council, and almost all showed clinical signs suggestive of vitamin deficiency. Blood ascorbic acid values were low in about half.—F. C. Aitken.

KRUISINGA, R. J. H. De zogenaamde chlorosis tarda met dysphagie. [**So-called *chlorosis tarda* with dysphagia.**] *Nederland. Tijdschr. Geneesk.*, 1955, **99**, 1907–1911. [Acad. Ziekenhuis, Groningen.] English summary.

This syndrome, characterised by atrophy of the mucosa of tongue and pharynx, perlèche, brittle nails, loss of hair, histamine-refractory achlorhydria and Fe-deficiency anaemia, is subject to great variation in its manifestations. Anaemia is by no means always present. In a special study 4 patients with the highest number of signs were investigated for deficiency of riboflavin, folic acid and vitamin B_{12}, without definite result. Nor was there obvious abnormality in excretion of 17-ketosteroids. Always the mouth was small and there was difficulty in swallowing.—I. Leitch.

Vitamin A

1011

ADAM, A. and GUTHEIL, H. Vitamin A-Bilanzversuche bei Säuglingen. [**Vitamin A balance experiments with infants.**] *Ztschr. Kinderheilk.*, 1955, **76**, 462–475. [Kinderklin., Univ. Erlangen.]

Vitamin A was estimated in the faeces of infants, aged from 2 weeks to 7 months, receiving a diet of cow's milk. In 6 infants with diseases which did not affect their nutritional condition the percentage of the ingested vitamin which was excreted ranged from 0 to 17·5. In 6 dystrophic children the percentage was higher, ranging from 10 to 83. The highest excretion was found in a patient with carbohydrate dystrophy. In 4 premature infants the percentage excreted was, respectively, 3·7, 28, 29·2 and 71. Very small amounts were excreted by 3 infants fed on human milk, which was alleged to be about 3 times as rich in the vitamin as winter cow's milk. When vitamin A was added to cow's milk to bring the content up to 4000 I.U. per litre, the amount in the faeces was usually greater in total amount, but the changes in the percentage excretion after fortification were inconsistent. In a child of 2 years with cerebral palsy and sepsis, no vitamin appeared in the faeces after moderate amounts of vitamin A and only 1 per cent. after high doses. When 50 out of 100 young infants attending the clinic were given vitamin A the percentage incidence of infections was 18 compared with 35 among untreated infants. The average daily weight gain was 21 per cent. higher in the infants given the vitamin than in those not given it.

NEUWEILER, W. Über die intestinale und placentare Resorption des Vitamins A in Form der wasserlöslichen Arovit-Tropfen " Roche ". [**Absorption of vitamin A in the form of water-soluble Arovit (Roche) from the intestine and placenta.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26**, 87–91. [Frauenklin., Univ. Berne.] English and French summaries.

Vitamin A and carotene were estimated in the venous blood of mothers, in venous and arterial umbilical cord blood, and in the placenta. For 4 women who were not given vitamin A the average values per 100 ml. were 160 μg. carotene and 202 I.U. vitamin A in maternal blood, 13 μg. and 77 I.U. in venous cord blood, 32 μg. and 50 I.U. in arterial cord blood, and in placenta 12 μg. and 43 I.U. per 100 g. [The values are given as I.U. per cent. in 10 cm^3. or 10 g. but seem about the expected values for I.U. per 100 ml. or 100 g.] In 8 mothers who were given 300,000 I.U. vitamin A as an aqueous preparation a few hours before parturition much higher values were found. The maternal blood averaged 117 μg. carotene and 292 I.U. vitamin A, venous cord blood 14 μg. and 99 I.U., arterial cord blood 44 μg. and 252 I.U. and the placenta 36 μg. and 135 I.U. The values both with and without vitamin A were much higher than those obtained in similar studies by the same author in 1943 (Abst. 1755, Vol. 15). The higher results in those not given vitamin A are ascribed to the improved state of nutrition throughout the population, and the higher results after vitamin A to its administration in aqueous and not in oily medium.—T. Moore.

GONZALEZ OUTON, P. M. Hipervitaminosis A aguda en niños de edad prepuberal. [**Acute poisoning with vitamin A in children before puberty.**] *Medicamenta*, 1955, **24**, 70–71. [San Fernando, Cadiz.]

Two children aged 9 and 11 years presented acute signs of vitamin A intoxication, characterised by headache and flushing of the face, within 2 days of receiving a water-soluble preparation providing 400,000 I.U. vitamin A and 600,000 I.U.

vitamin D. The onset was sudden and recovery occurred spontaneously.—A. M. Copping.

1014

GERMERAAD, W. F. and VASHBINDER, H. (with VERBEEK, A. M. T. A. and VAN DER SIJDE, H. R.) De behandeling van acne vulgaris met vitamine A. [**Treatment of acne vulgaris with vitamin A.**] *Nederland. Tijdschr. Geneesk.*, 1955, **99**, 2358–2363. [Centrale Org. Bestrijd. Huidziekten, Rotterdam.] English summary.

In an outpatient department, 234 patients with acne vulgaris were treated with very large doses of vitamin A. In addition 40 were given dummy treatment, and 60 who had improved with vitamin A were subsequently given dummies. Five different preparations of vitamin A were used; those most efficient in producing a high value for vitamin A in the blood were Arovit-Tropfenlösung (Hoffmann-La Roche) and the authors' own preparation of vitamin A acetate in solution in *iso*propanol. In order to achieve a cure, a vitamin A value of 300 I.U. ml. plasma had to be maintained for from 3 to 9 months, and the preparation had to be taken with absolute regularity. Injections of vitamin A were given to 3 patients, but they did not influence the vitamin A content of the blood. Blood vitamin A was estimated 433 times between 18 October 1950 and 12 April 1952. The test must be completed on the day the blood is drawn, otherwise the vitamin A content decreases. Sixty-three patients continued treatment for 9 months and 41 of them were cured. In the first 2 months the condition sometimes got worse. Hyperkeratosis or fissure of the lower lip sometimes appeared. Of the 40 patients given dummies, one-third had improved after from 3 to 4 months but did not lose their comedones, in contrast with those treated with vitamin A. The amount of vitamin A required to maintain a cure varied widely.

BECKMANN, R. Zur Kritik der alkalischen Serum-Phosphatase und ihres klinischen, diagnostischen Wertes für die Kinderheilkunde. [**Alkaline serum phosphatase and its clinical diagnostic value in paediatrics.**] *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1955, **7**, 14–58. [Kinderklin., Westfälische Wilhelms-Univ., Münster.] English and French summaries.

A general appraisal is made of the test, and the conclusion is reached that the value for alkaline serum phosphatase is of no value as a criterion of rickets.—E. M. Hume.

1016

CREERY, R. D. G. and NEILL, D. W. **Intake of vitamin D in infancy.** *Lancet*, 1955, **269**, 372–374. [Royal Belfast Hosp. Sick Child.]

It was thought desirable to ascertain the amounts of vitamin D regularly given to infants. Health visitors on their routine visit made inquiries about the amount and kind of milk, cereal and vitamin D preparation that were being given to infants aged 3 months in April or May 1955. The survey covered 90·1 per cent. of the babies of that age living in the City of Belfast. The total number included for analysis was 1087. No clinical assessment was made. Of the 1087 infants, 212 were being totally or partly breast fed, 176 were having liquid cow's milk, 351 were having national dried milk, and 348 proprietary brands of dried milk. All the dried milk preparations contained vitamin D. With these milks in the above order, the percentage having a vitamin D supplement was 74, 64·2, 70·9 and 75·6. The supplement most frequently used was Ministry of Food cod liver oil compound. Histograms are given for each type of feeding to show the number of infants receiving vitamin D daily, in amounts increasing by increments of 200 from 0 to 3000 I.U. Of all the infants, 10·8 per cent. had no vitamin D and 15 per cent. had less than 600 I.U. daily; these were almost entirely breast fed or given liquid cow's milk. The percentage getting from 600 to 1000 I.U. daily was 19, and from 1000 to 2000 I.U. daily 51; 4·2 per cent. had more than 2000 I.U. daily.

The daily amount recommended by the British Paediatric Association (*Arch. Dis. Child.*, 1943, **18**, 58, and Abst. 685, Vol. 13) is 700 I.U.; 25·8 per cent. of the babies were having less than that, and 55·2 per cent. were having more. It is suggested that the state of "idiopathic hypercalcaemia in infants with failure to thrive" (Absts. 1179, 1180, Vol. 25) may be associated with such high dosage. The policy is discussed which should be pursued to remedy insufficiency and excess; it is recognised that the second problem is particularly difficult to solve.—E. M. Hume.

1017

KALOUD, H. Vergleichende Untersuchungen über die Wirkung der intramuskulären Stosstherapie mit Vitamin D_2 und D_3 bei der Säuglingsrachitis. [**Comparative study on the efficacy of single-dose intramuscular treatment with vitamin D_2 and vitamin D_3 in infantile rickets.**] *Öst. Ztschr. Kinderheilk.*, 1955, **11**, 216–221. [Kinderklin., Univ. Graz.]

It was previously reported that there was more rapid healing of rickets with a single oral dose of 15 mg. vitamin D_3 than of vitamin D_2 (Abst. 2381, Vol. 24). In the present test the single dose of 15 mg. was given by intramuscular injection in oil

solution. Vitamin D_3 (Actifral D_3, Philips-Chemie, Vienna) was given to 13 children with severe rickets, and vitamin D_2 (Vi-De, Dr. A. Wander, Vienna) to 11. Rate of healing of craniotabes and of the distal ends of the radius and ulna as seen radiographically, and changes in serum Ca, P and alkaline phosphatase values were the criteria. In more rapid healing of craniotabes and in its ability to raise the product of the serum Ca and P values, vitamin D_3 proved superior.—E. M. Hume.

1018

JONXIS, J. H. P. **Some observations on rickets.** *Glasgow Med. J.*, 1955, **36,** 227–237. [Dept. Paediat., Univ. Groningen.]

Report of the Fleming Memorial Lecture, University of Glasgow, 5 May 1955.

1019

SCHLANGE, H. Rachitisprophylaxe und -therapie mit vitaminierter Milch in der Klinik. [**Prevention and treatment of rickets with vitaminised milk in the Klinik.**] *Monatsschr. Kinderheilk.*, 1955, **103,** 217–219. [Kinderklin., Freie Univ., Berlin.]

Vitamin D_3 (Merck, Bayer) was added in alcoholic solution to cow's milk and human milk to give a concentration of 1000 I.U. per litre. In the Klinik, between November 1953 and April 1954, 206 infants received the milk. Of 69 that had previously been treated with Vigantol, 2 had rickets on admission, and of 137 previously untreated, 15 had rickets. Fifty-one of the premature and 121 of the full-term babies were under observation for long enough to make a conclusion possible. Four of those treated prophylactically, 3 of them premature, were not protected, and 1 of those treated curatively did not heal. The use of vitaminised milk is strongly recommended as being without the disadvantages of an oil solution. There was some evidence that rickets was more frequent among babies previously fed on oatmeal gruel (*Haferschleim*).—E. M. Hume.

1020

CATHALA, J. and HENNEQUET, A. Sur la prophylaxie du rachitisme par les laits vitaminés. [**Prophylaxis of rickets with vitaminised milk.**] *Pédiatrie*, 1955, **10,** 215–225 (with discussion 225–226).

The question of providing milk fortified with vitamin D was discussed from the public health standpoint at a session of the Commission de Protection de l'Enfance du Conseil Permanent d'Hygiène Sociale et des Médecins Consultants Régionaux de Pédiatrie. On the basis of the arguments put forward, it was recommended that certified pasteurised milk, labelled as enriched with vitamin D and intended for consumption by infants, should be sold in sealed bottles. The level of fortification suggested was 400 I.U. vitamin D per litre. A variety of opinions was expressed by other members of the Commission and the proposal was rejected by 17 votes to 8.

The 2 patients were children of 8 months and 2 years. Their state was typical of vitamin D excess.—E. M. Hume.

1023

HALLMAN, N., TÄHKÄ, H. and AHVENAINEN, E. K. **High plasma calcium and influencing factors in interstitial plasma cell pneumonia in infants.** *Ann. Paediat. Fenn.*, 1954–55, **1,** 34–49. [Child. Clin., Univ. Helsinki.]

A series of 59 infants with interstitial pneumonia, 22 full-term and 37 premature, were grouped according to birthweight. Their plasma Ca values ranged from over 15 to 11·9 mg. per cent., but only 6 had values below 12·0, of whom 5 died; the highest values were in the infants with the lowest birthweights. All but one of the infants had been treated with 1 or more large intramuscular doses of vitamin D, followed by oral doses, to prevent rickets. High values for plasma Ca were found in infants that had received one or several large doses of vitamin D. Plasma P was always and alkaline phosphatase usually high. Differential diagnosis from vitamin D excess was based on X-ray examination of bones, blood chemistry, and the fact that blood Ca might fall while intensive treatment with vitamin D was in progress. Further, other premature infants that

had received the same high doses of vitamin D as the sick children had normal plasma Ca values.

1024

UEHLINGER, E. D-Avitaminose und renale Osteomalacie. **[Vitamin D deficiency and renal osteomalacia.]** *Schweiz. med. Wochenschr.*, 1955, **85**, 521–527. [Pathol. Inst., Univ. Zürich.]

An exhaustive post-mortem examination was made of 2 elderly, female patients, both dying with very severe osteomalacia, one of renal and one of nutritional origin. The latter had not left her room for 4 years and had lived chiefly on bread and tea without butter, and a little milk and small amounts of tinned meat and vegetables. She died before any treatment could be given. The patient with renal osteomalacia received considerable amounts of vitamin D before her death.

Anatomically the skeletal changes were identical. Both skeletons showed osteomalacia and *osteitis fibrosa*; fibro-osteoclasis was widespread. The similarity in the histological pictures too was remarkable. Hyperplasia of the parathyroid gland was present in the patient with renal osteomalacia but not in the other, and it is therefore concluded that fibro-osteoclasis can arise from causes other than parathyroid overactivity. Differential diagnosis of the two kinds of osteomalacia must depend on blood and urine tests.—E. M. Hume.

1025

SAVILLE, P. D., NASSIM, J. R., STEVENSON, F. H., MULLIGAN, L. and CAREY, M. **The effect of A.T. 10 on calcium and phosphorus metabolism in resistant rickets.** *Clin. Sci.*, 1955, **14**, 489–499. [Metabol. Unit, Inst. Orthopaedics, Royal Nat. Orthopaedic Hosp., Stanmore, Middlesex.]

Balance studies of Ca and P were made on 2 boys 5 and 9 years old, 2 girls of 6 and 12, a girl of 15, sister of the boy of 5, and a woman of 41, mother of the 2 last mentioned, all with resistant rickets, in order to assess the efficiency of A.T. 10 (dihydrotachysterol) in controlling the condition.

Administration of A.T. 10 in doses of from 1 to 10 mg. daily caused a rapid decrease in faecal Ca and P. In 4 of the patients there was no corresponding increase in the urinary excretion, so that the balance of Ca and P became strongly positive. In one patient rickets was already healing before the test; Ca and P in the urine increased but, even so, a more positive balance was established. In the sixth patient urinary Ca and P increased so rapidly that the balance was hardly changed. Addition of sodium phosphate to the diet raised serum P to about 5 mg. per 100 ml. and depressed serum Ca by about 0·5 mg. per 100 ml.; urinary Ca decreased and the balances for Ca and P became more strongly positive. Faecal Ca was not increased; if anything, it was reduced.

When one patient was given calciferol instead of A.T. 10, there was no difference in the balance. It is concluded that the action of A.T. 10 and calciferol is the same when the metabolic state of the patient is the same.

For adequate treatment of resistant rickets and to secure normal growth, it is recommended that phosphate be given as well as A.T. 10 or calciferol in order to maintain serum P at the level normal in childhood. Such treatment would have the further advantage of more easily keeping serum Ca below the toxic level.—E. M. Hume.

1026

SCHLESINGER, B., LUDER, J. and BODIAN, M. **Rickets with alkaline phosphatase deficiency: an osteoblastic dysplasia.** *Arch. Dis. Childhood*, 1955, **30**, 265–276. [Hosp. Sick Child., Great Ormond St., London.]

Three infants with signs of gross bone disorder resembling rickets are described. Radiographic differentiation from true rickets was based on the raising of the periosteum caused by early irregular formation of bone and the absence of cupping at the growing ends of the bones.

In the skull calcification was very poor and the growth of bone did not keep pace with that of the brain so that there was a bulging fontanelle and wide open sutures, which later showed premature fusion. In all 3 infants the alkaline phosphatase was much reduced and, in the one examined for bone phosphatase, activity was low. Serum Ca was raised in 2 of the infants; their kidney function was impaired and their blood urea was high. Serum P was moderately reduced. Histological examination of biopsy material from the skull and tibia showed disorganised architecture in the osteoid seams and few osteoblasts or osteoclasts at the margins of the trabeculae; the osteocytes also were reduced in number. Ethanolamine phosphate was found in the urine of one and in that of a sibling who at 6 weeks was found to have low serum alkaline phosphatase.

Treatment with large doses of vitamin D led to some improvement of calcification but did not affect the serum phosphatase level. Renal function improved as the value for serum Ca fell. All the parents appeared healthy. The few cases reported in the literature are reviewed. It is suggested that the condition may be familial and that the primary fault may be in osteoblast formation.—L. Wills.

Vitamin E

1027

GOUNELLE, H., FRANÇOIS, A., MARNEY, C. and ROBEY, M. Les variations de la vitaminémie

E au cours de la gestation et l'incidence du facteur saisonnier. [**Variations in vitamin E in blood during gestation and the effect of season.**] *C.R. Soc. Biol.*, 1955, **149**, 288–291. [Hôp. Bretonneau.]

Tocopherol was estimated 214 times in the blood of 178 pregnant women during the years 1951–54. When the results were grouped according to the period of pregnancy the average value in mg. per 100 ml. was for the first trimester 0·66, for the second trimester 0·75 and for the third 0·88. When the results were grouped according to the month of the year, irrespective of the period of pregnancy, evidence of seasonal variation was found, with the values at their lowest in spring and early summer.—T. Moore.

1028

KRAMER, M. Der Vitamin-E-Spiegel des Blutes während der Gravidität. [**Vitamin E values in the blood in pregnancy.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26**, 58–65. [Inst. Ernährungswissensch., Budapest.] French and English summaries.

Vitamin E was estimated, by a method which uses the Emmerie and Engel reaction, in the blood serum of pregnant and non-pregnant women. For 86 non-pregnant women the average value per 100 ml. serum was for vitamin E 0·99 mg., s.d. $\pm$ 0·25, and for carotene 131 μg, s.d. $\pm$ 49. Values for vitamin E rose as pregnancy progressed. One hundred women during the first trimester showed an average value for vitamin E of 0·96, s.d. $\pm$ 0·20, and for carotene of 132. Sixty-five women in the second trimester had an average value for vitamin E of 1·28, s.d. $\pm$ 0·28 and for carotene of 145. In the final trimester for 82 women the average value was for vitamin E 1·79, s.d. $\pm$ 0·30, and for carotene 180.—I. M. Sharman.

1029

A review.

1030

BÄUMER, A. and BECKMANN, R. Zur Bedeutung einer Vitamin E-Erniedrigung im Serum bei Leberkrankheiten. [**The meaning of low vitamin E values in the serum in liver diseases.**] *Klin. Wochenschr.*, 1955, **33**, 431–434. [Med. Klin., Univ. Münster.]

Tocopherol was estimated 173 times in the blood serum of 54 patients with liver diseases. The normal value was taken as about 1500 μg. per cent. with range from 1200 to 2000. In all the patients except 2 with primary carcinoma of the liver, the value was low, the highest value found at any time being below 1200. The lowest values were in patients with obstructive jaundice and jaundice of Meulengracht's type. In 10 patients the urinary excretion of 17-ketosteroids was measured before and after treatment with tocopherol. As the serum tocopherol value rose, the amount of ketosteroids excreted rose also and the patients felt much better, but the changes were not maintained if tocopherol was withdrawn.

OSTEN, W. Soll eine Vitamin-E-Behandlung mit Kalzium oder Magnesium kombiniert werden? (Eine klinische Studie zur Behandlung peripherer Gefäss-schäden.) [**Should treatment with vitamin E be combined with calcium or magnesium? A clinical study on the treatment of damage to peripheral blood vessels.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26**, 19–31. [Chirurg. Abt., Rudolf Virchow Krankenhaus, Berlin.] French and English summaries.

Twenty-one men and 3 women, mostly aged from 41 to 60 years and suffering from arteriosclerosis and other vascular abnormalities, were divided into 3 groups. All were treated with *dl*-α-tocopheryl acetate, orally or by intramuscular injection, in doses from 100 mg. daily to 600 mg. 3 or 4 times a week. One group in addition was given an intravenous injection of 1 g. calcium gluconate 3 or 4 times a week, and another had injections of the same amount of magnesium ascorbate. Progress was studied for 3 months by oscillography, skin thermometry, capillaroscopy and measurement of tolerance of heparin and thrombin, and from subjective reports. Weekly estimations were made of free and esterified cholesterol and of total phospholipins in the blood serum. The patients, classified as definitely improved, improved and uninfluenced, numbered 2, 4 and 2 in the group treated with tocopherol only, 0, 3, and 2 in the group treated with calcium also, and 6, 3 and 2 in the group treated with magnesium also. The ratio of total phospholipins to esterified cholesterol in the serum appeared to increase during treatment to a greater extent in the group given magnesium than in the other groups.—T. Moore.

Vitamin B Complex

1032

ORTAÑEZ, J. and PALILLO, L. **Better health through better rice.** *J. Philippine Med. Assoc.*, 1955, **31**, 33–36. [Manila.]

There are still 25,000 deaths annually from beriberi in the Philippines.

By the Dr. J. Ortañez process (patient pending), whole rice is soaked in a 0·1 per cent. suspension of $CaCO_3$ for 5 min. It is then steamed for 30 min. under 15 lb. pressure and dried in hot air.

When dry it can be milled in the ordinary way with little loss of minerals or vitamins. The retention of vitamin B_1 on milling is reported by the Public Health Research Laboratory to be 90 per cent., and the loss on washing is said to be only 3 per cent. The rice keeps well, swells more than ordinary rice when cooked and tastes as good. At present, rice thus treated costs 25 per cent. more than ordinary rice, but with increased production the cost should not be more than 5 per cent. greater. The economic importance is stressed of using a natural product instead of importing synthetic vitamin B_1 for fortification at the cost of dollars.—E. M. Hume.

1033

LIMBOS, P., BURETTE, E. and ROGOWSKY, M. Sur une forme particulière de béri-béri observée à Stanleyville. [**On a particular form of beriberi seen at Stanleyville.**] *Ann. Soc. belg. Méd. trop.*, 1954, **34**, 963–979. [Hôp. Congolais, Stanleyville, Belgian Congo.] Flemish summary.

It is reported that beriberi seems to have become more frequent in the Belgian Congo since the last war, particularly in military camps. From 1950 to 1953, 70 patients were seen; only one was seen in the first 8 months of 1954. All except 2 were males under middle age; two-thirds were soldiers. Six came from the school at Stanleyville. None of the patients was very poor. Dysentery, Flexner or amoebic, was often present. Oedema and nerve signs were relatively slight though pretibial oedema was usually present. Heart changes shown in the electrocardiogram and by X-ray were the most important signs. The condition responded well to intravenous injection of from 100 to 200 mg. vitamin B_1 daily, but there was often relapse when the vitamin was withdrawn. No death occurred. The diet was abundant in calories and did not appear to be notably deficient in vitamin B_1; carbohydrate as rice, manioc and bread was excessive. Contributory causes were probably dysentery and the drugs and antibiotics used to counteract it. An examination was made of all the 79 boys in the school where beriberi had been found in 6, and the conclusions drawn were confirmed.—E. M. Hume.

1034

TRINCÃO, C., PINTO, G. L., NOGUEIRA, A. R., GOUVEIA, E. and PARREIRA, F. A eliminação urinária da tiamina pelos indígenas da Guiné Portuguesa, normais ou doentes de ancilostomiase filariose e tripanosomiase. [**Loss of vitamin B_1 in the urine of natives of Portuguese Guinea, normal or suffering from ankylostomiasis, filariasis or trypanosomiasis.**] *An. Inst. Med. trop.*, 1955, **12**, 29–33. French and English summaries.

The excretion of vitamin B_1 was investigated in 6 normal subjects, 11 with ankylostomiasis, 7 with filariasis and 17 with sleeping sickness. Wide variations in the amount per ml. urine or per hour were recorded with no apparent difference between the different groups. There was no indication for treatment with vitamin B_1.—A. M. Copping.

DUSCHL, H. Über die unterstützende Behandlung der Intoxikation mit Cocarboxylase. [**Supporting treatment of toxic states with cocarboxylase.**] *Monatsschr. Kinderheilk.*, 1955, **103**, 236–238. [Städt. Kinderklin., Dortmund.]

Treatment with cocarboxylase is reported for infants in severe toxic states arising from nutritional upsets. In many such infants accumulation of pyruvic acid in the blood was a sign of general toxicosis with extreme dehydration due to diarrhoea and vomiting, and was difficult to relieve. Intravenous injection of cocarboxylase was preferred, since absorption from subcutaneous injection might be too slow in severe cases. The effect of cocarboxylase in restoring normal metabolism is discussed. Of 79 infants treated with it 10 died within the first few hours and were considered too ill to have responded. During the first 36 hr. only 8 others died, which was a low mortality rate for infants with severe toxic disturbances. The rapid initiation of treatment with cocarboxylase is recommended in all such conditions.—A. M. Copping.

ORSINI, M. and PAOLINI, A. Azione della cocarbossilasi sulla piruvemia nelle sindromi chetonemiche dell'infanzia, spontanee e provocate. [**Effect of cocarboxylase on the pyruvic acid content of the blood in children with spontaneous or experimentally produced ketonaemic syndromes.**] *Arch. ital. Pediat. Puericolt.*, 1955, **17**, 183–200. [Ist. Clin. Pediat., Univ. Rome.] French, English and German summaries.

See Abst. 4114, Vol. 25.

Pyruvic acid and ketone bodies were estimated before and for 4 hr. after a single intravenous injection of from 25 to 100 mg. cocarboxylase in 19 children aged from 5 months to 12 years, 5 of them with essential hyperketonaemia, 3 with diabetic ketosis, 2 with hyperketonaemia induced by diet, and the rest with secondary ketosis. The mean value for pyruvic acid in the blood for 10 normal subjects was 0·64 mg. per cent., with range 0·38 to 1·05. The values for the patients before treatment ranged from 0·8 to 3·6. A

small reduction of the blood value for pyruvic acid took place in 7 of the 19 subjects ; there was even less effect on the concentration of ketone bodies. The reduction of both values was greatest in 2 patients with carbohydrate dystrophy, in whom some degree of vitamin B_1 deficiency might have existed.—E. M. Hume.

MARTEN, G. Über Vorkommen und Verhalten des Thiamindisulfids im Stoffwechsel. [**Occurrence and behaviour in metabolism of vitamin B_1 disulphide.**] *Naturwissenschaften*, 1955, **42,** 443–444. [Anst. Vitaminforsch., Potsdam-Rehbrücke.]

Significant amounts of vitamin B_1 disulphide might occur in urine. After intravenous injection of 30 mg. of the substance an equilibrium with vitamin B_1 in the blood was established. Total excretion of vitamin B_1 took longer to reach its initial value after injection of vitamin B_1 disulphide than after injection of vitamin B_1.—D. Duncan.

SAMRUATRUAMPHOL, S. and PARSONS, H. T. **An anti-thiamine effect produced in human subjects by bracken ferns.** *J. Amer. Dietetic Assoc.*, 1955, **31,** 790–793. [Dept. Foods Nutrit., Sch. Home Econ., Univ. Wisconsin, Madison.]

In view of recommendations that bracken fronds be used as human food, the effect of eating young fern was studied in 2 groups of subjects having diets that supplied 1·6 or 1·25 mg. vitamin B_1 daily. The urinary excretion of the vitamin decreased when raw bracken fronds were eaten in salads, which was attributed to a decrease in its availability owing to enzymic breakdown into fragments not available to the human organism. Investigation *in vitro* showed the antivitamin B_1 factors in fern to be of two types, one heat-stable and the other heat-labile. The amount of the former varied little, but that of the latter increased as the fern crosiers began to unfold, and then decreased as the fronds matured.—A. M. Copping.

A review.

1040

ARMSTRONG, R. W. and GOULD, J. **The nature and treatment of delirium tremens and allied conditions.** *J. Mental Sci.*, 1955, **101,** 70–84. [Dept. Psychiat., Univ. Oxford.]

Fourteen patients were treated with B vitamins combined with vitamin C and glucose. The most rapid improvement followed the administration every 4 hr. of 1000 mg. vitamin B_1 hydrochloride, from 100 to 200 mg. nicotinamide and 1500 mg. ascorbic acid, preferably by vein. The effect of pyridoxine, riboflavin or pantothenic acid was less obvious. Delirium tremens may, it is suggested, be considered to result from vitamin deficiency which disturbs the carbohydrate metabolism of the brain and from the abnormal substitution of alcohol for glucose as the oxidisable substrate in the brain.—L. Wills.

SCHÖNBAUER, E. Schwere Dünndarmveränderungen bei Vitamin B-Mangelerscheinungen. [**Severe changes in the small intestine in presence of vitamin B deficiency signs.**] *Wien. klin. Wochenschr.*, 1955, **67,** 383–384. [Zentral-Röntgeninst., Allg. Krankenhaus, Univ. Vienna.]

A man of 54, an alcoholic, had severe ulcerative changes of the skin and of the mucous membrane of the mouth and gastro-intestinal tract, with loss of weight and blood in the stools. A barium meal showed great delay ; movement, secretion and tone of the gut were all impaired. Pellagra was suspected and treatment with B vitamins was given ; the response to a barium meal became normal in 4 days. An account of treatment and its results is to be given elsewhere. The object of the present contribution is to describe the behaviour of the gut after the barium meal.

GOLDSMITH, G. A., ROSENTHAL, H. L., GIBBENS, J. and UNGLAUB, W. G. **Studies of niacin requirement in man. 2. Requirement on wheat and corn diets low in tryptophan.** *J. Nutrition*, 1955, **56,** 371–386. [Nutrit. Res. Lab., Sch. Med., Tulane Univ., New Orleans, La.]

In a continuation of previous work (see Abst. 856, Vol. 23), 3 white female subjects received a mixed " wheat " diet providing 1600 to 2100 Cal. daily, containing 140 g. wheat flour products and providing approximately 5 mg. nicotinic acid and 200 mg. tryptophan. The only signs shown in 3 months were in 1 subject herpes on the lip and a slight redness of the tongue and in a second, lassitude and depression. In the third, characteristic signs

of deficiency of nicotinic acid were first seen after 80 days. In the earlier trials this subject and 2 others, receiving a "corn" diet which contained 89 g. maize products and 35 g. wheat flour and provided about 4·7 mg. nicotinic acid and 190 mg. tryptophan daily, had signs of deficiency in about 50 days.

On the wheat diet the excretion of N^1-methylnicotinamide decreased gradually throughout the experiment and that of the 6-pyridone of N^1-methylnicotinamide more rapidly; the decrease in excretion of the former was slower than had been noted on the maize diet.

One subject, a negro woman aged 46 years, received the wheat and maize diets alternately for periods of 20 days each. No constant difference was apparent between the 2 diets in their effects on the excretion of nicotinic acid metabolites.

Six subjects received the maize diet supplemented with extra nicotinic acid so that the total ranged from 4·6 to 21·2 mg. daily. Up to the amount of from 8 to 10 mg. daily, about 0·2 mg. nicotinic acid metabolites was excreted for each mg. of the vitamin ingested; above that value the amount was about 0·6 mg. It is suggested that an intake of from 8 to 10 mg. nicotinic acid daily will "prevent depletion of body stores when the diet contains corn and furnishes 200 mg. tryptophan".

With both the wheat and the maize diet the time in which pellagra developed seemed to be related to the intake of nicotinic acid and tryptophan per unit of body size, but it is concluded that the relationship "may not explain completely the differences in clinical and laboratory findings between the two regimens", and that the presence in maize of an inhibitory factor influencing the requirement of nicotinic acid cannot be ruled out.

TOMABECHI, K. **The conversion of L- and D-tryptophan to niacin in human body.** *J. Vitaminol., Japan,* 1954, **1,** No. 2, 18–23. [Dept. Nutrit., Inst. Pub. Health, Minato-ku, Tokyo.]

Excretion of N^1-methylnicotinamide, nicotinic acid and methylnicotinamide-6-pyridone was measured in a healthy young man having a diet containing 0·98 g. tryptophan and 23·9 mg. nicotinic acid. A marked increase in excretion of nicotinic acid and its derivatives occurred within 24 hr. of a dose of 2 g. L-tryptophan. When D-tryptophan was given the rise in the amount of nicotinic acid derivatives was smaller and the maximum excretion was delayed until the second day. If nicotinamide was given a rapid increase of excretion followed. It thus seemed that man could utilise D-tryptophan, which it had previously been thought could not be converted into nicotinic acid.—A. M. Copping.

EICHINGER, O., KEMMERER, G. and MEINERS, S. Kardiale Störungen bei Alactoflavinose. [**Heart lesions in riboflavin deficiency.**] *Klin. Wochenschr.*, 1955, **33,** 397–405. [Med. Abt., Städt. Krankenhaus, Aschaffenburg.]

Since signs of riboflavin deficiency are frequently associated with signs of cardiac insufficiency the existence of a causal relationship between the 2 conditions was investigated. An intensive study was made of 14 patients with mild cardiac insufficiency in whom major signs were lacking: tests such as electrocardiography were used to assess any improvement from treatment. Improvement in the heart condition as well as the disappearance of any sign of riboflavin deficiency followed the administration of the vitamin. Certain patients were given glucosides either before or after the vitamin treatment, and it appeared that their mode of action was not the same as that of riboflavin. Riboflavin deficiency may in itself cause cardiac lesions, and cardiac insufficiency by its secondary effects on the intestinal function may produce vitamin deficiency, so establishing a vicious circle.—L. Wills.

1046

RUSSO, G. L'elettrocardiogramma nelle sindromi da carenza prevalentemente riboflavinica, consecutive ad enteropatie diarroiche. [**The electrocardiogram in deficiency syndromes, chiefly of riboflavin, after diarrhoeal disease.**] *Pediatria,* 1954, **62,** 676–709. [Clin. Pediat., Univ. Palermo.] English, French, German and Spanish summaries.

The study was made on 22 children from 3 to 24 months old. The clinical findings, which were suggestive of riboflavin deficiency, are tabulated. The condition of 6 babies resembled kwashiorkor. Characteristic changes in the electrocardiogram were present in almost all. Administration of riboflavin brought about some improvement, but aureomycin was more effective.—E. M. Hume.

1047

IINUMA, S. **Synthesis of riboflavin by intestinal bacteria.** *J. Vitaminol., Japan,* 1954, **1,** No. 2, 6–13. [Biochem. Lab., Kitasato Inst., Minato-ku, Tokyo.]

Studies of urinary and faecal excretion of riboflavin were made with a human subject who ate a normal diet in weeks alternating with a week on a vegetable diet and one on a meat diet. Excretion on a normal diet was fairly constant. With a vegetable diet the amount of riboflavin in the faeces increased fivefold but that in the urine increased only slightly. When meat predominated there was less riboflavin in the faeces and more in the urine.—A. M. Copping.

1048

BERGER, H., WEBER, J. R., ANTENER, I. and PFÄNDLER, U. Schwere Ariboflavinose, Spätrachitis und Amindiabetes bei chronischer erblicher Koproporphyrie. [**Severe deficiency of riboflavin, late rickets and loss of amino-acids in chronic, hereditary coproporphyria.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26**, 96–129. [Kinderklin., Univ. Berne.] French and English summaries.

A boy of 8 years was seen with stunted growth, signs of riboflavin deficiency and severe rickets; bilateral cataract and hyperkeratosis suggested vitamin A deficiency. Serum and saturation tests suggested multiple vitamin deficiency which was asymptomatic in spite of the deficiencies mentioned above. There was no evidence that the vitamin deficiencies were due to faulty absorption. The rickets healed normally when vitamin D was given. The response to riboflavin was subnormal and to prevent relapse continuous treatment was necessary. The excretion of coproporphyrin III in the stools and urine was 50 to 100 times the normal. There was also a great increase in the excretion of amino-acids in the urine, especially of glycine, and oxalic acid was always present. Both parents, who were cousins, and an aunt on one side of the family and an uncle on the other excreted coproporphyrin III in excess of normal and had a moderate increase in the amount of amino-acids in the urine. The pathogenesis and etiology are discussed at length. It is suggested that the marked and persistent riboflavin deficiency was the result of the increased synthesis of coproporphyrin since riboflavin is necessary for the formation of the porphyrins. The need for continuous treatment with riboflavin supported the view and the relationship was shown also by the finding that during treatment with riboflavin the urinary output of the vitamin increased while that of the porphyrins decreased and vice versa. The possibility that the severe rickets might be related to interference with growth by deposition of porphyrin in the calcifying zones of the bones is discussed; such a deposit of the isomers of uroporphyrin I has been reported in patients with chronic porphyria. With symptomatic treatment and continuous administration of riboflavin, growth and general condition were maintained at a satisfactory level.—L. Wills.

BEAN, W. B., HODGES, R. E. and DAUM, K. (with BRADBURY, J. T., GUNNING, R., MANRESA, J., MURRAY, W., OLIVER, P., ROUTH, J. I., SCHEDL, H. P., TOWNSEND, M. and CHU TUNG, I.) **Pantothenic acid deficiency induced in human subjects.**

THORNTON, G. H. M., BEAN, W. B. and HODGES, R. E. **The effect of pantothenic acid deficiency on gastric secretion and motility.** *J. Clin. Invest.*, 1955, **34**, 1073–1084; 1085–1091. [Metabol. Unit, Dept. Med., State Univ. Iowa.]

The diet used to produce deficiency contained granulated sugar, maize starch, vitamin-free casein, water, maize oil, cystine, a salt mixture and added vitamins other than pantothenic acid, and was free from cholesterol and cholesterol esters. Three healthy subjects were maintained on the diet, which was given by stomach tube, for the following times: 12 days' control period during which a daily supplement of 30 mg. pantothenic acid was given; 25 days on the basic diet with the addition of 500 mg. ω-methylpantothenic acid, an antagonist to pantothenic acid; 6 days on the same regime with the addition of 4000 mg. pantothenic acid; 10 days on a well balanced diet with the addition of 1000 μg. vitamin B_{12} for 2 days, double the quantity of the other vitamins and, in addition, cortisone to combat the deterioration in the subjects' condition; and finally 14 days on the basic diet with the daily addition of 2000 mg. pantothenic acid.

During the period of deprivation there was no change in the skin or mucous membranes, but great mental depression developed; by the 13th to 16th day there was numbness and tingling of the hands and later paraesthesia became severe. One of the subjects showed weak dorsiflexion of the feet; all had hyperactive deep tendon reflexes and weakness of the extensor muscles and the interossei of the hands; they were unable to walk on tiptoe. All these motor changes cleared up slowly when the deficiency ended. The gastrointestinal changes are reported separately below. Signs of cardiovascular instability developed. All subjects while deficient had repeated upper respiratory infections which cleared up immediately when pantothenic acid was given. Biochemical investigation showed acetylation of excreted *p*-aminobenzoic acid to be nearly normal, but in a previous experiment with 1 subject a fall in acetylation to 50 per cent. from 70 to 80 per cent. occurred. The insulin tolerance test showed increased sensitivity, liver function appeared normal, α_1- and α_2-globulins rose in 2 men, the normal decrease in eosinophils caused by adrenocorticotropic hormone was impaired, cholesterol and its esters in the blood fell but the diet was devoid of cholesterol, urinary excretion of 17-ketosteroids decreased, vitamin C in the plasma and urine fell and excretion of vitamin B_1 and nicotinic acid rose. The eosinophil count rose. The addition of pantothenic acid to the diet did not correct all these abnormalities in the 6 days for which it was given before the clinical condition of the

subjects necessitated the change to a well balanced diet and administration of cortisone. There was considerable individual variation in the response to deprivation. Adrenal cortical function could not be tested, as consumption of large amounts of water caused diarrhoea.

An exhaustive examination was made of gastric function. Details of the methods used are included. In 2 of the subjects given Hunt's sucrose phenol red test meal, secretion of both parietal and non-parietal components of the gastric juice was greatly reduced during the period of pantothenic acid deficiency, and gradually recovered during the 3 following periods when pantothenic acid was being administered; the secretion of pepsin was unaffected. After histamine and insulin, secretion of both components and pepsin was low during the deficiency period, and there was a gradual recovery later. The changes in gastric secretion in the third subject were similar but less marked. Gastric motility showed no significant change. It is suggested that the decrease of gastric secretion may result directly from the effect of coenzyme A deficiency on the parietal cells or indirectly through altered adrenal cortical activity.—L. Wills.

PELLEGRINI, U. and CHIARI, G. La determinazione microbiologica dell'acido pantotenico. Il tasso della vitamina nel latte di donna. [**Microbiological estimation of pantothenic acid. Concentration of the vitamin in human milk.**] *Internat. Ztschr. Vitaminforsch.*, 1955, **26,** 32–58. [Ist. Clin. Pediat., Univ. Parma.] German, French and English summaries.

After an extensive review, values for pantothenic acid in human milk and in cow's milk and colostrum are collected from the literature and tabulated.

Pantothenic acid was estimated with *Lactobacillus arabinosus* 17/5 by the method of Skeggs and Wright (Abst. 3207, Vol. 14) in the samples of milk, in some of them after enzymic digestion. From 37 women in the first to 47th week of lactation attending hospital in Parma, 101 samples of milk were obtained. The mean values for individuals in μg. per ml. ranged from 1·18 to 2·80 without enzymic digestion, and from 1·54 to 3·55 with it. The values were lowest in colostrum and rose gradually during the first week to a level which was then maintained, with fluctuations, throughout.—E. M. Hume.

ZARTMAN, E. R., BARNES, A. C. and HICKS, D. J. **Observations on pyridoxine metabolism in pregnancy.** *Amer. J. Obstet. Gynecol.*, 1955, **70,** 645–649. [Dept. Obstet. Gynaecol., Ohio State Univ., Columbus.]

The degree of pyridoxine deficiency was judged by the amount of xanthurenic acid excreted in the urine in 10 hr. beginning 2 hr. after an oral dose of 10 g. tryptophan. In all, 48 subjects were studied. The average excretion in men and non-pregnant women was 17 mg. and in normal pregnant women at all stages of pregnancy and immediately after delivery it was 251 mg. After an oral dose of 50 mg. pyridoxine given 7 to 10 hr. before the test, similar pregnant women and 4 of those previously tested excreted on the average only 13 mg.; when 4800 mg. aspirin was given to pregnant women instead of pyridoxine, excretion of xanthurenic acid was variable but in no instance was it depressed to within the normal range. Nicotinic acid had no effect on the excretion of xanthurenic acid. No deficiency was detected in the newborn infant but the results were inconclusive.

1052

SMALL, M. D., ZAMCHECK, N., VITALE, J. J., LONGARINI, A. and FISHER, B. **The effect of pyridoxine hydrochloride in acute alcoholic intoxication.** *J. Lab. Clin. Med.*, 1955, **46,** 12–20. [Long Island Hosp., Boston, Mass.]

In 5 normal males and 6 chronic alcoholics the intravenous injection of 0·5 to 2·0 g. pyridoxine had no consistent effect on the degree of alcoholic intoxication as judged by the general clinical condition and the results of certain psychological and physiological tests.—L. Wills.

1053

LIVINGSTON, S., HSU, J. M. and PETERSEN, D. C. **Ineffectiveness of pyridoxine (vitamin B_6) in the treatment of epilepsy.** *Pediatrics*, 1955, **16,** 250–251. [Dept. Paediat., Johns Hopkins Sch. Med., Baltimore, Md.]

Pyridoxine in doses increasing from 40 to 100 mg. daily was given to 31 children with cryptogenic or secondary epilepsy of varying severity. In all but 1 of 6 children tested the tryptophan load test was normal. None of the children treated showed any improvement though in 21 of them the fits were later controlled by orthodox treatment.—L. Wills.

1054

SHVEDSKII, V. P., TEPLYAKOVA, Z. G. and KOSTINA, A. K. Letzenie spru folievoi kislotoi v komplekse s drugimi metodami terapii. [**Treatment of sprue with folic acid in combination with other methods.**] *Klin. Med., Mosk.*, 1955, **33,** No. 2, 38–46. [Inst. Perelivan. Krovi, Tashkent.]

Under treatment with folic acid, 0·02 g. 3 times daily for 20 days, signs and symptoms of sprue disappeared and normal blood regeneration

occurred. In patients with sprue and anaemia resembling pernicious anaemia reduction of mitotic activity and maturation of red and white cells improved; hyperchromic changes disappeared and the blood picture became normal. Folic acid, therefore, should always be given in addition to routine treatment, which consists in a prescribed diet, blood transfusion and injections of liver.

TASKER, P. W. G. **Correlation of serum-vitamin B_{12} levels and urinary folic acid in nutritional megaloblastic anaemia.** *Lancet*, 1955, **269,** 61–63. [Inst. Med. Res., Kuala Lumpur, Malaya.]

In 29 patients with uncomplicated nutritional megaloblastic anaemia, vitamin B_{12} was estimated in the serum, and folic acid in the urine, after a single dose of 5 mg. folic acid had been given subcutaneously, and again after 15 days during which the patients received 15 mg. folic acid parenterally daily; the 5 mg. test dose was then given by mouth. The value for vitamin B_{12} in the serum was low in 10 of the patients. In a series of 15 patients with a similar degree of normoblastic anaemia the range of urinary folic acid was estimated to establish a norm. In the patients with megaloblastic anaemia the excretion of 8 was low after the subcutaneous dose of folic acid and of 11 after the oral dose. There was a close and significant correlation between the value for vitamin B_{12} in the serum and the amount of folic acid in the urine after the subcutaneous but not after the oral dose. When the serum vitamin B_{12} was low the excretion of folic acid was, in many cases, low also; in such patients there may have been deficiency of both vitamins.—L. Wills.

1059

BOGER, W. P., WRIGHT, L. D., STRICKLAND, S. C., GYLFE, J. S. and CIMINERA, J. L. **Vitamin B_{12}: correlation of serum concentrations and age.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 375–378. [Dept. Res. Therap., Norristown State Hosp., Pa.]

Vitamin B_{12} was estimated microbiologically in serum from 528 apparently healthy persons of all ages with *Lactobacillus leichmannii* as test organism. Agreement with results obtained with *Euglena gracilis* was good and recovery of added vitamin B_{12} was satisfactory. Though the variation in each age group was considerable the results for both men and women showed a significant trend towards lower serum values in old age. The mean serum vitamin B_{12} for all the subjects was 560 $\mu\mu$g. per ml., the 95 per cent. confidence limits being 70 and 1060 $\mu\mu$g. per ml., respectively. Exceptionally, very high values occurred for which no explanation could be found.—L. Wills.

1060

LEVY, W. and WIDROW, S. A. **A case of megaloblastic anemia associated with steatorrhea and the celiac syndrome.** *J. Pediat.*, 1955, **47,** 100–104. [Paediat. Serv., Morrisania City Hosp., New York.]

Severe megaloblastic anaemia associated with signs of coeliac disease in a child of 2 years responded haematologically to 15 mg. folic acid given parenterally but treatment with a modified coeliac diet was required to improve the bowel signs. There was no relapse over 7 years, so it was concluded that the coeliac syndrome was a manifestation of the anaemia. The case was the first one of megaloblastic anaemia in a child in about 23,000 admissions during 26 years.—L. Wills.

SWAN, H. T., REISNER, E. H. (Jr.) and SILVERMAN, M. **The effect of various metabolites on the growth of marrow cells in vitro.** *Blood, J.*

Hematol., 1955, **10**, 735–752. [Div. Haematol., Dept. Med., Post-Grad. Med. Sch., Univ. New York.]

Cultures of megaloblastic marrow cells from patients with pernicious anaemia were grown on chick plasma clots, on glass slivers and in suspension in different media, including human serum and various additions. Cell growth was stimulated by vitamin B_{12} in cultures on plasma clots in pernicious anaemia serum. In cultures in pernicious anaemia serum on glass, addition of vitamin B_{12} converted megaloblastic into normoblastic haemopoiesis. In normal serum the glass cultures showed maturing normoblasts. In suspensions in pernicious anaemia serum folinic acid, but not vitamin B_{12}, caused an increase in nucleated cells. Combination of intrinsic factor with vitamin B_{12} did not enhance the effect of the vitamin. Colchicine inhibited the effect of folinic acid on suspensions of megaloblastic cells, and inhibited growth of normoblastic marrow suspensions in autologous serum. Amethopterin, too, inhibited growth of normoblastic marrow suspensions; the inhibition was reversed in presence of folinic acid. The observations seemed to suggest that the effect of folinic acid was to stimulate mitosis in suspension cultures. Normoblasts grown in pernicious anaemia serum diluted with saline produced megaloblastic cells; amethopterin had the same effect on suspensions in normal serum.—A. M. Copping.

UNGLAUB, W. G. and GOLDSMITH, G. A. **Oral vitamin B_{12} in the treatment of macrocytic anemias.** *Southern Med. J.*, 1955, **48**, 261–268 (with discussion 268–269). [Div. Nutrit., Dept. Med., Sch. Med., Tulane Univ., New Orleans, La.]

In 5 patients with pernicious anaemia in relapse and in 2 untreated patients with nutritional macrocytic anaemia, a satisfactory initial haematological response followed a single oral dose of 3000 μg. vitamin B_{12} in aqueous solution. The vitamin was given to the patient fasting, and no food was allowed for the following 4 hr. Another patient with pernicious anaemia in relapse was given only 500 μg.; there was a submaximum but sustained response. Maintenance treatment with 3000 μg. in aqueous solution once every 4 weeks or 1000 μg. in tablet form once a week gave a satisfactory haematological and clinical state in most of the 14 patients treated, but for some the dose had to be adjusted, as with parenteral treatment. Oral therapy was effective also in treating neurological signs when they were present. Two patients with nutritional macrocytic anaemia relapsed when treatment was withdrawn although their diet was apparently adequate. Low serum values for vitamin B_{12} were found in all the untreated patients, but they returned to normal after oral treatment.—L. Wills.

1065

YAVORKOVSKII, L. L. Blizhaishchikh rezultatakh lecheniya vitaminom B_{12} pri bolezni Addison-Birmera. [**Short-term results of treatment of Addison-Biermer's disease with vitamin B_{12}.**] *Klin. Med., Mosk.*, 1955, **33**, No. 2, 22–26. [Gematol. Otdel, Rizhsk. Respublik. Klin. Bolnit., Riga.]

The effect of vitamin B_{12} in patients with Addisonian pernicious anaemia was equal to that of an active liver preparation. A starting dose of 15 to 30 μg. induced normoblastic transformation of the bone marrow, usually in 48 hr. Reticulocytes reached their peak on the fourth to the sixth day and rapid improvement, chiefly of the red cells, followed; the rise of Hb was less until Fe was given. As a rule 150 to 195 μg. vitamin B_{12} taken over 2 to 3 weeks induced a remission which was incomplete in regard to erythropoiesis; further treatment with liver preparations improved the red cell count. Moderate symptoms of funicular myelosis with paraesthesia and defects of sensation disappeared or diminished after treatment. Although further trial is required to assess the optimum dosage of vitamin B_{12} and to find a rational method of combined long-term treatment and to prevent nervous system changes, there is good reason to believe that this drug merits a place in the treatment of pernicious anaemia.

ROSENBLUM, C., WOODBURY, D. T., GILBERT, J. P., OKUDA, K. and CHOW, B. F. **Comparative absorption of vitamin B_{12} analogues by normal humans. 1. Chlorocobalamin vs. cyanocobalamin.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 63–66. [Res. Labs., Merck and Co., Rahway, N.J.]

Absorption of vitamin B_{12} was measured by the excretion test of Schilling (Abst. 3675, Vol. 24) in subjects receiving by mouth 2 μg. chlorocobalamin or cyanocobalamin labelled with ^{60}Co. Chlorocobalamin was less well absorbed than cyanocobalamin, but both compounds, when injected in massive doses, were equally effective in liberating absorbed labelled cobalamins into the urine. It is suggested that differences in the rate of absorption of the analogues might be caused by differences in their electrolyte properties.—A. M. Copping.

1069

BLACKBURN, E. K., COHEN, H. and WILSON, G. M. **Oral treatment of pernicious anaemia with a combined vitamin B_{12} and intrinsic factor preparation.** *Brit. Med. J.*, 1955, ii, 461–463. [Dept. Haematol., Sheffield Royal Infirmary.]

The preparation used contained 6 μg. crystalline vitamin B_{12} and 30 mg. intrinsic factor per tablet. For the treatment of patients in relapse 5 tablets daily were given; the maintenance dose was 1 tablet daily. Four out of 5 previously untreated patients responded well to the treatment; one failed to respond, although she responded well to the same dose of vitamin B_{12} given parenterally. After 12 months of maintenance treatment with the oral preparation, 11 out of 12 patients previously maintained at a satisfactory level with vitamin B_{12} given parenterally showed a significant fall in the Hb and red blood cell values. Another patient while taking the tablets developed signs of subacute combined degeneration which disappeared when vitamin B_{12} was given parenterally. On clinical grounds and on account of the relatively high cost of oral compared with parenteral treatment, the latter remained the treatment of choice.

GLASS, G. B. J., BOYD, L. J., LUHBY, A. L. and STEPHANSON, L. (with JONES, E. L., ROSEN, S. and LAUGHTON, R. W.) **Assay of intrinsic factor preparations: comparison of the hepatic uptake of radio-active Co^{60}-B_{12} with the hematopoietic response in pernicious anemia.** *J. Lab. Clin. Med.*, 1955, **46**, 60–73. [Gastroenterol. Res. Lab., Dept. Med., New York Med. Coll., Flower and Fifth Avenue Hosps.]

The potency of 14 different preparations of intrinsic factor from pig's stomach was tested independently by measuring the uptake by the liver of vitamin B_{12} containing ^{60}Co (see Abst. 1215, Vol. 25) in 8 patients with pernicious anaemia in remission and, with the help of other investigators, by the classical haemopoietic response method in 20 patients in relapse. On 3 of the latter, 5 preparations were tested by both methods. With 11 preparations where the isotope method showed definite positive or negative activity the haemopoietic response method gave similar results, but with 3 preparations where the isotope method gave only slightly positive results the correlation with the haemopoietic response was unsatisfactory. Possible explanations for the discrepancies are suggested. The usefulness of the isotope method was thus clearly shown and its advantages are discussed. It is particularly stressed that it could be used on patients in remission.

SCHILLING, R. F., CLATANOFF, D. V. and KORST, D. R. **Intrinsic factor studies. 3. Further observations utilizing the urinary radioactivity test in subjects with achlorhydria, pernicious anemia, or a total gastrectomy.** *J. Lab. Clin. Med.*, 1955, **45**, 926–934. [Dept. Med., Med. Sch., Univ. Wisconsin, Madison.]

For previous parts see Absts. 1115, 3675, Vol. 24.

Tests for the presence of intrinsic factor were based on the appearance of radio-activity in the urine after radio-active vitamin B_{12} had been given by mouth (see Abst. 3675, Vol. 24). In the work now reported gastric juice was used as source of intrinsic factor. In 18 subjects with no evidence of pernicious anaemia the mean radio-activity of the 24-hour urine was 14·2 per cent. of the test dose with range from 7 to 22. In 31 patients with achlorhydria but no suggestion of pernicious anaemia the corresponding value was 11·6 with range from 2·2 to 29·5; 9 of these subjects excreted less radio-activity than the smallest amounts excreted by the subjects with no evidence of pernicious anaemia. Duplicate estimations in 11 subjects showed satisfactory agreement, so that any difference in excretion after administration of intrinsic factor or other single substance was attributed to the effect of that substance. In 35 patients with pernicious anaemia the mean activity of the 24-hr. urine was only 0·6 per cent. of the radioactivity of the test dose, with range 0 to 2·3. When intrinsic factor was added to vitamin B_{12} the mean value was 10·0 per cent. with range 3·1 to 30·0. The low values for some of the patients when given intrinsic factor were tentatively explained as due to an insufficient dose of intrinsic factor or to low intestinal permeability. The findings in 13 patients who had been subjected to total gastrectomy were like those in patients with pernicious anaemia; 2 of them had had an end-to-end oesophago-duodenostomy so that there was no

blind loop to account for the pernicious-anaemia-like blood picture, which suggested that in human subjects the stomach is the only site for production of intrinsic factor.—L. Wills.

1072

CALLENDER, S. T. and EVANS, J. R. **Observations on the relationship of intrinsic factor to the absorption of labelled vitamin B_{12} from the intestine.** *Clin. Sci.*, 1955, **14,** 387–393. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

The absorption of ^{60}Co-vitamin B_{12} was measured by the amount of radio-activity in the faeces after a standard oral dose of less than 0·02 μC. of activity. In 4 control patients with free HCl in their gastric juice the amount of radio-active vitamin B_{12} absorbed increased with increasing doses of vitamin B_{12} up to about 1·0 μg.; above that dose further increase did not increase absorption. In 4 patients with pernicious anaemia in remission and 1 untreated, the absorption of vitamin B_{12} increased in proportion to the size of the dose of intrinsic factor up to 100 mg. but doses from 200 to 1000 mg. did not increase the absorption. When 4000 mg. of intrinsic factor was given with the standard dose of radio-active vitamin B_{12} to patients with pernicious anaemia or control subjects, absorption of the radio-active vitamin was less, probably because of the considerable amount of vitamin B_{12} present in most intrinsic factor preparations. In the pernicious anaemia patients when the amount of vitamin B_{12} and of intrinsic factor was increased concurrently, the absorption of the vitamin increased only to about the same extent as in the control subjects. In patients with steatorrhoea and defective absorption, much larger doses of intrinsic factor than those effective in pernicious anaemia were necessary to increase absorption. In a patient who had suffered removal of the proximal half of the jejunum amounts of intrinsic factor up to 1000 mg. did not increase the absorption of the test dose of radio-active vitamin B_{12}.—L. Wills.

1073

ELLENBOGEN, L., WILLIAMS, W. L., RABINER, S. F. and LICHTMAN, H. C. **An improved urinary excretion test as an assay for intrinsic factor.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 357–362. [Nutrit. Physiol. Sect., Amer. Cyanamid Co., Pearl River, N.Y.]

The 24-hr. urinary excretion of radio-activity was measured after a single oral dose, given fasting, of 2 μg. ^{60}Co-vitamin B_{12}. No food was given for 2 hr. Immediately after the dose a flushing dose of from 1 to 4 mg. unlabelled vitamin B_{12} was given parenterally and repeated daily while urinary collections were being made.

The mean amount of ^{60}Co-vitamin B_{12} excreted in the urine during the first 24 hr. in 22 healthy subjects was 11·7 per cent. of the dose, and significant amounts were excreted during the second and third days. In 35 patients with pernicious anaemia in remission only 0·17 per cent. was excreted on the first day and there was no significant excretion on the second or third day, but when 50 mg. of an intrinsic factor preparation known to be active curatively in a daily dose of 25 mg. was given with the radio-active vitamin B_{12} the mean excretion during the first 24 hr. rose to 6·1 per cent. and significant amounts were excreted on the second and third days. To test the activity of an intrinsic factor preparation the excretion of active vitamin B_{12} was first estimated with a preparation of known potency and then with the preparation under test; the tests must be made on pernicious anaemia patients, who need not be in relapse. When large doses of inactive vitamin B_{12} were used for flushing, the excretion of radio-activity was greatly reduced in normal subjects but not in patients with pernicious anaemia. In 2 patients when 500 mg. of intrinsic factor preparation containing only negligible amounts of vitamin B_{12} were used instead of 50 mg., more radio-activity was excreted than after the small dose; in one of these patients the maximum excretion after either dose of intrinsic factor was delayed. The flushing method enables several tests to be made consecutively on the same patient.—L. Wills.

JOSKE, R. A., FINCKH, E. S. and WOOD, I. J. **Gastric biopsy: a study of 1,000 consecutive successful gastric biopsies.** *Quart. J. Med.*, 1955, **24,** 269–294. [Clin. Res. Unit, Walter and Eliza Hall Inst. Med. Res., Melbourne.]

Biopsy samples were obtained from 623 subjects, mostly patients for investigation for possible gastro-intestinal disease, with some healthy subjects. Histological examination showed a

continuous graduation from a normal mucosa through all grades of gastritis to complete atrophy. Good correlation was found between the clinical diagnosis and the histological picture. Atrophy was generally symptomless and any degree of gastritis might be present without symptoms. Apart from patients with carcinoma the frequency of gastritis increased with age but a normal mucosa was found in 13·4 per cent. of patients over 70 years of age. Of 100 patients examined with pernicious anaemia, none was without some degree of atrophic gastritis, classified as severe in 35 and as gastric atrophy in 40. No relation could be established between the presence of gastritis and nutritional status.—L. Wills.

HELLE, J. and OHELA, K. **Treatment of herpes zoster neuralgia with massive doses of vitamin B_{12}.** *Ann. Med. exp. Biol. Fenn.*, 1955, **33,** 116–121. [Dermatol. Clin., Univ. Helsinki.]

Three similar groups, 2 of 19 and 1 of 9, patients with severe pain from herpes zoster were treated by local therapy alone or with 10 intramuscular doses of 1000 μg. vitamin B_{12} or 10 intramuscular doses of 150 mg. vitamin B_1. There was no significant difference between the 3 groups in the time the pain persisted.—L. Wills.

1078

HAMPP, H. Vitamin-B_{12}-Behandlung in der Neurologie vornehmlich bei Schmerzzuständen. [**Treatment with vitamin B_{12} in neurology, especially in painful conditions.**] *Deutsch. med. Wochenschr.*, 1955, **80,** 1139–1140. [Nervenklin., Univ. Munich.]

In 33 patients suffering from diseases of the nerves associated with pain, such as trigeminal neuralgia, herpes and tabes, treatment with vitamin B_{12} relieved or removed the pain. The duration of treatment ranged from 1 to 7 weeks and the total dose ranged from 2500 to 20,000 μg., with a mean dose of 9380 μg., according to the severity and duration of the disorder.—L. Wills.

1079

MONTOYE, H. J., SPATA, P. J., PINCKNEY, V. and BARRON, L. **Effects of vitamin B_{12} supplementation on physical fitness and growth of young boys.** *J. Appl. Physiol.*, 1955, **7,** 589–592. [Phys. Fitness Res. Lab., Michigan State Coll., Lansing.]

Two groups of 16 boys aged from 12 to 17 years living in an institution were given daily for 7 weeks a capsule containing 50 μg. vitamin B_{12} or a dummy capsule. A comparable group of 19 boys had no supplement. The boys in the first 2 groups were paired on their ability to run for half a mile. Age, height and weight and results of the Harvard step test were recorded before and after the 7-week period. Wetzel grid records were kept. Competitive running of the half mile three times a week resulted in a weight loss in comparison with a group of boys who did not run. Vitamin B_{12} had no effect on the capacity to run, but in some thin subjects the weight loss was greater in those who received dummy capsules.—A. M. Copping.

SOMESWARA RAO, K., RAMANATHAN, M. K., TASKAR, A. D. and PHANSALKAR, S. V. **The failure of vitamin B_{12} to promote growth in undernourished Indian children.** *Indian J. Med. Res.*, 1955, **43,** 277–283. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Two trials of the effect of vitamin B_{12} on growth were made with 26 destitute Indian girls, once when the diet taken was grossly insufficient in energy value and protein as well as in Ca, vitamin A and the vitamin B complex, and once after 12 months of an improved diet, the energy value of which was still slightly below the girls' needs. Administration of 25 μg. vitamin B_{12} daily by mouth for from 14 to 15 weeks to half the children in each trial produced no demonstrable effect on growth, and nitrogen retention was not increased. In experiments by other workers food was given to appetite, but in the present trials the energy intake was both fixed and low.—L. Wills.

Vitamin C

1081

DODIN, A. Parasitoses intestinales et avitaminoses C. [**Intestinal parasite infestation and vitamin C deficiency.**] *Méd. trop.*, 1955, **15,** 322–328. [Groupe Mobile d'Hygiène, Corps de Santé Colonial.]

Observations on the native schoolchildren of the east coast of Madagascar showed a high incidence of gingival haemorrhage and of cramp on exertion. Vitamin C excretion tests and examination of the stools for parasites in 51 of the children showed that of 38 children infested with intestinal parasites all failed to excrete a normal amount of the vitamin after a test dose and that 3 in whom parasites were not found also failed to do so. Ten children who excreted a normal amount of the vitamin were all free from intestinal parasites. Ascaris and other parasites were found to destroy vitamin C *in vitro* and the larger the worm, the greater the degree of destruction.—L. Wills.

HOITINK, A. W. J. H. Vitamin C en arbeid. Onderzoekingen over den invloed van arbeid en van vitamine C-toediening op het menschelijk organisme. [**Vitamin C and work. Studies on the influence of work and of vitamin C intake on the human organism.**] *Verhandeling Nederlands Inst. Praevent. Geneesk.*, 1946, No. 4, pp. 176. English summary.

The work was exercise on a bicycle ergometer (to be described) against a known resistance, at constant speed, to exhaustion, the measure of performance being resistance in watts × time in minutes. Each experimental subject was tested 3 times: (1) before being given vitamin C, (2) after taking, usually, 300 mg. vitamin C (Redoxon Roche) daily for a week, sometimes after 2 weeks and a somewhat higher total of vitamin C and (3) again, usually after 1 or 2 weeks. Blood was taken before and after the exercise for biochemical and haematological studies, and urine after an interval. The results are presented in summary tables and the statistical analysis in similar detail.

The effects of vitamin C and of work are described separately. The effect of vitamin C was to increase the amount of work done. It increased also the vitamin C concentration of blood and urine; it reduced blood sugar, blood red cell count, blood Hb, pulse rate, respiration rate and systolic blood pressure. There was no effect on blood glycogen, inorganic P of blood and urine, blood Ca, blood lactic acid, creatine in urine, number and distribution of leucocytes in blood, diastolic blood pressure or pulse pressure. The effect of work, independent of vitamin C administration, was to increase vitamin C in blood and urine, blood sugar and lactic acid, inorganic P in blood and urine, creatine in urine, blood leucocytes with a change in distribution, pulse rate, respiration rate, and pulse pressure (followed by a fall); to reduce haematocrit and blood pressure, systolic and diastolic; other measurements showed no change.

It is argued that saturation with vitamin C improves performance, as training does. In general, performance increased with haematocrit readings.—I. Leitch.

1084

WINSEMIUS, W., JANSSEN-VAN DER SCHOOT, E.R.B., DONATH, W. F. and DE WAART, A. Vitamine C en geestelijke arbeid. [**Vitamin C and mental work.**] *Verhandeling. Nederlands Inst. Praevent. Geneesk.*, 1954, No. 25, pp. 45. English summary.

To complete the investigation begun by Hoitink (see previous Abst.) on the effect of vitamin C on physical work, a study was made in similar circumstances of the effect of 300 mg. vitamin C daily for 4 weeks, on performance in 2 trials, a modified Bourdon Wiersma test, and a proof reading test. Before each trial vitamin C was estimated in blood, and in morning urine for which it was expressed as mg. per g. creatinine.

There were 3 groups of 11, 12 and 12 healthy male medical students, without tablets, with dummy tablets and with vitamin C tablets. Tests were made 4 times, the initial, and at intervals of 2 weeks, the last 2 weeks being without tablets. On the average all the groups were unsaturated with vitamin C at the beginning; the group given vitamin C tablets was saturated at the second and third but not at the fourth test.

There was great improvement with practice in the Bourdon Wiersma test; none in the proof reading. Vitamin C had no effect on performance of either test. The statistical analysis of the results is reported in detail.—I. Leitch.

1085

ČOP, D. **ACTH (small doses) and C-vitamin in the treatment of chronic rheumatic inflammations.** *Bull. sci. Yougoslav.*, 1955, **2**, 60. [Central Municip. Inst. Rheumatism, Zagreb.]

Daily doses of from 6 to 10 mg. adrenocorticotropic hormone, to a total of from 300 to 600 mg., with from 4 to 6 g. ascorbic acid daily, to a total of from 100 to 600 g., were given to 50 rheumatic patients. Twelve of 14 with ankylosing spondylitis and 26 of 35 with rheumatoid arthritis improved.—A. Hepburn.

1086

CHEKIN, V. YA. Obmen vitamina C pri travma. [**Metabolism of vitamin C in injuries.**] *Sovet. Med.*, 1955, No. 4, 70–71. [Bolnit. Vorkutsk, Komi ASSR.]

In an attempt to clarify the problem of vitamin C metabolism in subjects with delayed wound healing, 25 patients admitted to the surgical ward 30 min. to 3 hr. after injury were the subject of a special study of the vitamin C content of plasma and urine. In most of them the level of ascorbic acid in plasma fell in the first 24 hr. and large quantities were excreted in the urine. After 6 days the level of vitamin C in the plasma rose, but so did urinary excretion; of 2 patients with normal levels of vitamin C in plasma excretion in the urine was 3 times normal in one and one and a half times in the other. All patients were given 3500 mg. ascorbic acid intravenously; after 7 days the plasma level rose only slightly in 6 and did not reach normal values. Excretion in the urine remained high. In 8 patients the plasma level was below that immediately after their injury, and excretion in the urine was higher. In the remaining patients the plasma level had returned nearly to normal but urinary excretion was above

normal. The results obtained suggest that the retention of vitamin C administered intravenously is poor. Losses in the urine were especially great after severe injuries of the central nervous system, which suggests that the central nervous system plays an active part in vitamin C metabolism.

LANCIANO, O. and MAGNANELLI, P. Azione dell'inositolo e della rutina sulle modificazioni del quadro capillariscopico prodotte dalla ialuronidasi. [**Effect of inositol and rutin on the changes produced by hyaluronidase on the capillariscope picture.**] *Bol. Soc. ital. Biol. sper.*, 1954, **30,** 972–974. [Clin. Pediat., Univ. Rome.]

Hyaluronidase injected subcutaneously had the effect of increasing the number and width of the capillaries and of causing petechial haemorrhages.

Hyaluronidase was injected subcutaneously into 8 children simultaneously with 5 mg. inositol, into 7 children with 1 mg. rutin, and into other children separately or with water. The capillaries at the site of injection showed the changes characteristic of hyaluronidase and, up to 24 hr., rutin or inositol had very little power to counteract them.

DIBENEDETTO DELL'AQUILA, M. and MINERVA, V. "Vitamina T" ed assorbimento intestinale del ferro. Ulteriore contributo sull'azione esercitata dall'acido folico e dalla vitamina B_{12}. [**"Vitamin T" and absorption of iron from the intestine. A further study of the action of folic acid and vitamin B_{12}.**] *Acta vitaminol.*, 1955, **9,** 121–127. [Ist. Clin. Med. Gen., Univ. Bari.] French, English German and Spanish summaries.

Nine subjects, normal from the haematological standpoint, were given 1 g. reduced iron by mouth. Two days later the dose was repeated with 5 ml. of a vitamin T preparation given by mouth at the same time and 5 ml. 2 hr. later. After another 2 days the test was repeated with 6 of the subjects, given 20 mg. folic acid in place of vitamin T. Blood was taken every 2 hr. up to 6 hr. after the dose of Fe, and serum Fe was estimated. In all the subjects but one the values increased more with vitamin T than without it. The increase with folic acid was more than without it in 4 of the 6 subjects but was usually less than with vitamin T.

When Fe was given intravenously as ferrous gluconate to 2 subjects, and the rest of the procedure was the same, the rise in serum Fe was less with vitamin T or folic acid than without them.

The preparation of vitamin T is stated to contain vitamin B_{12}, folic acid, folinic acid, *Lactobacillus helveticus* factor and deoxyriboside.—E. M. Hume.

DENTAL DISEASES

1091

DAVIES, T. G. H. and PEDERSEN, P. O. **The degree of attrition of the deciduous teeth and first permanent molars of primitive and urbanised Greenland natives.** *Brit. Dent. J.*, 1955, **99,** 35–43. [Royal Dent. Coll., Copenhagen.]

The degree of dental attrition was recorded in Greenland in 4 communities graded according to the extent of their urbanisation. The amount of wear was classified in 4 grades and mean values are presented for all deciduous teeth examined in children in age groups 2 to 3, 4 to 5, 6 to 7 and 8 to 9 years. They ranged from 0·78, 1·50, 1·77 and 1·91 in the most primitive to 0·00, 0·00, 0·25 and 0·26 in the completely urbanised community. In these 2 extreme areas, upper first permanent molars also were examined at older ages and although attrition increased with age in both groups its inverse relation to degree of urbanisation again appeared.

Possible causes are discussed, but no completely satisfactory explanation of the variation could be offered.—D. Harvey.

1092

HURTARTE E., A. and SCRIMSHAW, N. S. **Dental findings in a nutritional study of school children in five Guatemalan highland villages.** *J. Dent. Res.*, 1955, **34**, 390–396. [Inst. Nutrit. Central America and Panama (INCAP), Guatemala.]

Dental examination of 442 schoolchildren aged from 6 to 14 years in 5 villages at altitudes between 4700 and 6800 feet within an hour's drive of Guatemala City showed that their teeth were relatively good despite complete absence of dental care and retardation of height and weight (Abst. 2361, Title 4980, Vol. 24) and of bone development by U.S. standards. The diets are stated to be very low in animal protein and fat and in vitamin A and riboflavin, but are thought to be adequate in energy, vitamin B_1 and nicotinic acid. Ca intake is from 520 to 810 mg. daily, much from tortillas, which supply nearly 65 per cent. of the protein and 70 per cent. of the energy.

Caries was mostly in the deciduous teeth; in the permanent teeth there was a slow increase with age, but the average incidence as found by dental explorer was still under 2 per child at age 13. Differences between boys and girls did not reach significance. By U.S. standards permanent teeth were at least a year late in appearing. The incidence of gingivitis ranged from 3·7 per cent. at age 7 to 9·8 [7·8 in Table 1, p. 393] at age 13; it was ascribed to poor dental hygiene, not to nutritional deficiency. No significant difference was found in total protein, riboflavin, ascorbic acid, carotene, vitamin A, vitamin E and alkaline phosphatase contents of the serum of children with or without caries or gingivitis. The F content of the water was 0·4, 0·5 and 0·7 p.p.m. in 3 of the villages. No mottling due to fluorosis was seen. Sunshine is plentiful. The low incidence of caries is possibly due to the small amounts of refined carbohydrate consumed. The teeth of the adults were not investigated but were obviously bad.—W. M. Deans.

1093

PEACOCK, B. **Observations on the oral conditions of native races in British North Borneo.** *Brit. Dent. J.*, 1955, **99**, 87–89; 129–132; 207–208.

The first and second instalments of this article by one who recently spent 3 years as the only qualified dentist in the little-known colony of British North Borneo include matter of nutritional interest; the third deals with dental treatment only.

The country is about the size of Ireland but the population is thought to be only about 360,000. Indigenous peoples are the Dusuns, in the plains wet-rice farmers, in the hills growers of dry rice, but not settled, and the Muruts, primitive hunters with the blow-pipe and growers of dry rice on the shifting system. Malay fishermen live on the coasts and lower reaches of the rivers, and Chinese tradesmen and craftsmen in and about the towns. The staple food of all races is rice, flavoured with broth or small pieces of vegetable, fish or meat. Sago and tapioca also are popular. Protein intake is low by Western standards. Milk could be produced but little is used; "most natives do not regard it as a food and some regard it as an abomination", yet condensed milk, preferably sweetened, finds a ready sale even in remote parts. Little meat is used, usually that of the water buffalo, though in some areas cattle are numerous. The Malays live mainly on rice and fresh fish. Inland, fish is mostly sun-dried and may be months old. The Muruts eat jungle game, fish, crocodile and even rats and mice. The Chinese are by far the best cooks, but their food, though tasty, is all cut up into small pieces and requires little mastication. They use the water in which rice has been boiled as a drink or as medicine. All races eat coconut and use the oil and milk. Fruit is eaten to quench thirst rather than as a food, and taboos are frequent, *e.g.*, some tribes abhor pine-apple. Vegetables, the usual tropical kinds, are not very abundant. Sweet foods are popular with all; most of the sugar is imported. Certain Dusuns, especially pregnant women, eat earth from special patches of ground, thought to contain fuller's earth. All but the Malays, who are Moslems, brew liquor from rice, and sometimes thereby run short of food.

The Dusuns and Muruts mutilate the teeth and chew betel. They are fairly free of caries, but gingivitis is common. The condition of the deciduous teeth is variable; the best seen were on an inland plateau with basalt subsoil, which may indicate the presence of fluorine. On the whole the Malays have the best teeth, with little caries in the temporary dentition. The teeth of the Chinese children are very bad; this is ascribed to poor nourishment of the mothers, coupled with lots of sweet sticky food.—W. M. Deans.

THERAPEUTIC AND PREVENTIVE DIETETICS

GENERAL

1096

La alimentication en los hospitales dependientes del Ministerio de Asistencia Social y Salud Publica. 2. Las variantes de la alimentacion de accion dietoterapica. [**Diet in hospitals supported by the Ministry of Social Aid and Public Health. 2. The adaptation of therapeutic diets.**] *Inst. Nac. Nutricion, Argentina*, 1954, Publ. Cient. C.N.P. 34, pp. 138.

For part 1 see Abst. 2274, Vol. 24.

This second booklet deals with adaptations of diets for specific purposes; the bland diet, the low-residue diet and diets low in fat, carbohydrate, protein, purines or Na. The composition and energy value of each diet is given, then a list of foodstuffs with the net and crude requirements per patient daily, suggestions for preparation and daily menus. Local food preferences are taken into account.

Part 3 will deal with the diet in tuberculosis.

D. Duncan.

1097

BADR EL DIN, M. K. **Management of food intolerance in infantile wasting.** *J. Egypt. Med. Assoc.*, 1955, **38,** 93–101. [Fac. Med., Univ. Alexandria.]

Wasting from undernutrition, caused by poverty and ignorance, accounted for 16·5 per cent. of the total admissions to Alexandria University Hospital for sick children in 1952. Methods of treating the condition are discussed, and a trial is described in which 41 infants that had lost at least 30 per cent. of weight were divided into 4 groups. All were given the same dietary management, which aimed at supplying a complete diet, and one received in addition repeated blood transfusions, another had the same with 4 doses daily of from 15 to 25 mg. aureomycin, another had the aureomycin only, and another had no additional treatment. With no supplement progress was slow and 2 patients made none. Blood transfusions were of little help, but aureomycin either with or without blood transfusions promoted rapid gain of weight.—E. M. Hume.

1098

TALLERMAN, K. H. **The diet of the child in illness and convalescence.** *Practitioner*, 1955, **175,** 31–36. [Child Dept., London Hosp.]

A general account is given of the treatment by diet of children in acute and chronic illness and in convalescence. Particular aspects of treatment in kidney disorders, infective hepatitis, fibrocystic disease of the pancreas, diabetes, obesity, cyclical vomiting, threadworm infestation and coeliac disease are discussed. Recipes are given for bread, biscuits and cakes free from gluten and suitable for children with coeliac disease.

F. C. Aitken.

1099

SNYDER, C. H. **Practical scheme for fluid and electrolyte therapy in children.** *J. Amer. Med. Assoc.*, 1955, **158,** 1004–1006. [Ochsner Clin., New Orleans, La.]

In the scheme described 5 different solutions are used: 5 per cent. glucose, 10 per cent. invert sugar, 3*M* NaCl, 3*M* KCl and 1*M* sodium lactate. Once each day a suitable mixture of these solutions is prepared to provide for the patients' needs for 24 hr. The amounts of fluid and electrolytes for daily maintenance, correction of dehydration and replacement of current abnormal losses are expressed in terms of surface area, bodyweight and volume of fluid loss, respectively.—F. C. Aitken.

1100

MANTZ, J. J. C. Iets over dieetvoorschriften. [**On prescribing diets.**] *Voeding*, 1955, **16,** 606–619. [Voorlichtingsbur., Voedingsraad, The Hague.] English summary.

This general article pleads for greater accuracy in the prescription of diets. The National Research Council's recommended allowances for healthy persons should be kept in mind and varied according to the patient's nutritional state and circumstances. His dietary habits and financial position should be considered and emphasis laid on permitted rather than on forbidden foods. Full use of milk, if necessary salt-free, should be made.

M. Eddison.

1101

ROBINSON, C. H. **The sodium-restricted diet.** *Amer. J. Clin. Nutrit.*, 1955, **3,** 339–343. [Dept. Food Nutrit., Coll. Home Econ., Drexel Inst. Technol., Philadelphia, Pa.]

Details are given of foods permitted and forbidden in diets in which Na, not just table salt, is to be restricted; a suggested meal pattern and a sample menu are provided. It is emphasised that diets restricted in Na are often inadequate in Ca, riboflavin, protein, Fe and vitamins of the B group, and suggestions are made to avoid this and to provide variety. The nutritive values of the foods used in the basic diet and the way in which the Na content of the basic diet can be modified without difficulty are shown.—G. F. Garton.

1102

OLMSTEAD, E. G., CASSIDY, J. E. and MURPHY, F. D. **The use of beer in the low salt diet with special reference to renal disease.** *Amer. J. Med. Sci.*, 1955, **230,** 49–53. [Sch. Med., Marquette Univ., Milwaukee, Wis.] Interlingua summary.

Hospital diets containing 250 and 500 mg. Na were replaced in the treatment of 9 patients by diets with the same Na content but containing 1150 and 1530 ml. beer, respectively. As judged by clinical condition and renal function, treatment with the beer diets for 5 or 10 days, and in one case for 1 year, had no adverse effect. The beer diets were more palatable than the usual low-Na diets.—F. C. Aitken.

SPIESS, H. Lang wirksame Insuline beim Diabetes mellitus des Kindes. [**Long-action insulins in diabetes mellitus in children.**] *Deutsch. med. Wochenschr.*, 1955, **80,** 1170–1172. [Kinderklin., Univ. Göttingen.]

Satisfactory control was achieved in 14 of 21 diabetic children between 5 and 13 years of age by a single daily morning injection of "Lente" or "Long" insulin, generally from 20 to 40 units, combined with a diet supplying, according to age, protein 1 to 3, fat 1 to 2 and carbohydrate 4 to 7 g. per kg. bodyweight daily, the carbohydrate being taken mostly at the mid-day and afternoon meals. Hypoglycaemic attacks were rare. Careful medical

supervision is necessary. Children with diabetes not easily controlled by the older types of insulin were excluded from the trials.—W. M. Deans.

1111

DE TONI, G. La croissance de la taille chez les enfants atteints par le diabète sucré. Le Nanisme insulaire ou syndrome de Nobécourt. [**Growth in height of diabetic children. Islet dwarfism or Nobécourt's syndrome.**] *Acta paediat.*, 1954, **43,** Suppl. 100, 594–607. [Clin. Méd. Infant. "G. Gaslini", Univ. Genoa.]

The growth pattern of 32 children, in whom diabetes was diagnosed at the clinic between 1942 and 1953, was studied by the author's system (Title 1457, Vol. 20). For the dwarfism which, for some unknown reason, appears in some the name Nobécourt's syndrome is proposed. Details are given of 2 well-defined cases.—D. Harvey.

1112

ELZAS, M. De behandeling van diabetes. [**The treatment of diabetes.**] *Nederland. Tijdschr. Geneesk.*, 1955, **99,** 2808–2814. [Rotterdam.]

A review.

1113

COLWELL, A. R. **Selection of therapy in diabetes mellitus with illustrative case reports.** *Med. Clins. N. Amer.*, 1955, **39,** 39–54. [Dept. Med., Northwestern Univ. Med. Sch., Chicago, Ill.]

1114

ENGLESON, G. **Studies in diabetes mellitus.** *Acta paediat.*, 1954, **43,** Suppl. 97, pp. 162. [Paediat. Clin., Univ. Lund.]

Possible causes of the late complications of diabetes were studied in 217 adults and 42 children. These observations, with the evidence gleaned from an extensive review of the literature, suggested that the development of late complications is influenced by impairment of liver function and by endocrine factors and that unrestricted diet contributes to these.—F. C. Aitken.

1115

GOODMAN, J. I. **Etiology of the diabetic neuropathies.** *Amer. J. Digest. Dis.*, 1955, **22,** 236–239. [Cleveland Heights, Ohio.]

Atherosclerosis, vitamin deficiency and diabetes are discussed as possible causes; it is believed that the last plays the dominant part in the etiology of diabetic neuropathies.—F. C. Aitken.

GASTRO-INTESTINAL CONDITIONS

1116

KELLER, W. and MARGET, W. Untersuchungen zur Ätiologie und Pathogenese der akuten Durchfallserkrankungen mit Ernährungsstörung. 1. [**Etiology and pathogenesis of acute diarrhoeal disorders with disturbance of nutrition. 1.**]

KELLER, W. and BIESALSKI, P. Untersuchungen zur Ätiologie und Pathogenese der akuten Durchfallserkrankungen mit Ernährungsstörung. 2. [**Etiology and pathogenesis of acute diarrhoeal disorders with disturbance of nutrition. 2.**] *Ztschr. Kinderheilk.*, 1953, **74,** 95–118; 1955, **76,** 514–530. [Kinderklin., Univ. Freiburg i. Br.]

An attempt is made in these papers to clarify the relations of digestive disturbance in infants to infections and to feeding. (See Keller's classification of "akute Ernährungsstörungen", Abst. 4959, Vol. 23.)

1. Bacteriological examination of stools of 582 infants in hospital showed that, after *Bacteria coli* infections were accounted for and allowance was made for other pathogenic bacteria and viruses, there was a residue of diarrhoeal disorder to be ascribed to feeding. The term "akute Durchfallserkrankung mit Ernährungsstörung" is proposed instead of "akute Ernährungsstörungen".

2. A 3-year study of infection with fever showed that dyspepsia occurred much more frequently with "influenzal infection" than with other, even severer infections. Droese's work (Abst. 2408, Vol. 22) and further work to be published has shown that fat absorption is impaired in infants with influenzal infection. The possible sequence of events leading to diarrhoeal disorder is discussed. Even if infection is the primary cause, feeding is still of the greatest importance.—I. Leitch.

1117

POLAK, M. and PONTES, J. F. Zur Diagnostik der Steatorrhoe. [**Diagnosis of steatorrhoea.**] *Gastroenterologia*, 1955, **83,** 224–233. [Hosp. das Clin., Med. Fak., São Paulo.] English and French summaries.

Comparison of the results of studies of fat balance over 4 and 12 days in normal subjects and in patients with steatorrhoea showed that in most a 4-day period was adequate for the diagnosis of steatorrhoea. Estimations of the fat content made after the stools had been stored on ice for 4 days agreed well with those made on the day of collection. Estimations based on the Nile blue reaction or microscopical examination did not agree well with the results obtained from the balance studies.—L. Wills.

1118

WALLENSTEN, S. **The relation between sideropenia and anemia and the occurrence of postcibal symptoms following partial gastrectomy for peptic ulcer.** *Surgery*, 1955, **38**, 289–297. [Dept. Surg., Serafimerlassarettet, Stockholm.]

Postcibal signs and symptoms such as fatigue, pallor, nausea, palpitation, epigastric pain and diarrhoea are common after removal of part of the stomach. They were found to be positively correlated with the presence and degree of anaemia or low serum Fe values, especially the latter. Treatment with intravenous Fe gave improvement in 20 and complete disappearance of the signs and symptoms in 14 out of 21 patients with low serum Fe, and dramatic but temporary improvement in one man with normal Hb value, red cell count and serum Fe.—D. Duncan.

1119

KILLING, F. Sekundäre Sprue nach subtotaler Dünndarmresektion. [**Secondary sprue after subtotal resection of the small intestine.**] *Deutsch. Ztschr. Verdauungs- u. Stoffwechselkr.*, 1955, **15**, 113–122. [Inn. Abt., Krankenhaus "Huyssens-Stiftung", Essen.]

Report of a case.

THYROID DISEASE

1120

DE WIJN, J. F. Vergelijkend onderzoek naar de lichamelijke groei en ontwikkeling van struma- en struma-vrije schoolkinderen. [**Comparative study on the bodily growth and development of schoolchildren with and without goitre.**] *Maandschr. Kindergeneesk.*, 1955, **23**, 132–143. [Sectie Kinderhyg., Afd. Gezondheidszorg, Nederlands Inst. Praevent. Geneesk., Leyden.] English summary.

Examination was made in 1953 of 63 boys and 61 girls without goitres, and of 59 boys and 65 girls with goitres, all aged from 9 to 12 years, from different social levels [location not stated]. The proportion of well nourished children was higher among those with goitres than among those without. There was no difference in height, weight, or skeletal development between the groups. Both groups were below standard in weight but not in height. The development of secondary sex characters was retarded by about one year in both boys and girls with goitre. Systolic blood pressure was higher in the boys with goitre, but not in the girls. There was no difference in Hb values. The levels of inorganic P and alkaline phosphatase in serum were higher in children with goitre than in those without.

E. M. Hume.

1121

DONOSO, F., JADRESIC, A., LOPEZ C. E., CARCIA DE LOS RIOS, M. and ATRIA, P. Encuesta de bocio de las escuelas del Departamento de Melipilla. [**Enquiry on goitre in the schools of the Department of Melipilla.**] *Rev. méd. Chile*, 1955, **83**, 246–249. [Dept. Endocrinol., Hosp. San Juan de Dios.]

The incidence of goitre in 3167 children at 41 schools in the Department of Melipilla was 530, or 14·65 per cent. In the isolated region of Alhué, 100 of 280 pupils were affected. The goitre was usually of diffuse type.

A plea is made for more widespread examinations of this sort in Chile.—D. Duncan.

1122

JÄRVINEN, K. A. J. and LEIKOLA, E. **Non-toxic or simple goitre. Frequency among patients in wards for internal diseases at Helsinki.** *Ann. Med. int. Fenn.*, 1955, **44**, 31–40. [3. Med. Clin., Univ. Helsinki.]

Clinical examination for goitre was made in 10,557 patients over 15 years of age in hospital in Helsinki for internal diseases. The validity of the clinical assessment was checked at autopsy in 440 of the patients who died not more than 6 months later. The clinical assessment was correct in 398 of them. The tendency was almost always to underestimate the size of the goitre, and in 43 cases it was missed altogether. Nodules at least as large as a pea were found *post mortem* in the thyroid glands of 104 patients, in only 43 of whom they had been detected in life. It is concluded that the clinical examination recognised rather more than half (52·5 per cent.) of the existing goitres.

Of the total patients examined in life 6137 were female and 3980 male; the number of goitres found was 684 and 187, respectively. On the basis that only about half the goitres that exist are clinically recognised, the percentage incidence was 16 for both sexes, 22 for women and 10 for men. Very many of the patients were not born in Helsinki, but the proportion with goitre of those born there was greater than of those born elsewhere.—A. M. Copping.

1123

HERNÁNDEZ FELICIANO, M. El bocio endemico en la Isla de San Miguel de la Palma. [**Endemic goitre on the island of San Miguel de la Palma.**] *Rev. clín. española*, 1955, **57**, 162–174. English German and French summaries.

Goitre is prevalent on the island of La Palma in the Canaries. The report describes 274 cases, 95·2 per cent. of them women. The syndrome is predominantly hyperfunctional, with nervousness, high B.M.R. and exophthalmos. The goitre was

diffuse in 73 per cent. and nodular in the rest. There was one cretin without goitre. In affected areas the water supply is exceptionally low in I, with from 0·11 to 0·22 μg. per litre, and contains 1·7 to 11·5 mg. Ca per cent.—D. Duncan.

ANAEMIA

1124

GAISFORD, W. and JENNISON, R. F. **Intramuscular iron in infancy.** *Brit. Med. J.*, 1955, ii, 700–704. [St. Mary's Maternity Hosp., Manchester.]

Imferon, an iron-dextran complex, given intramuscularly, has been used successfully in treating over 100 infants with anaemia, in preventing anaemia of prematurity, and for infants before or after operations. No side effect was noticed.

F. C. Aitken.

1125

WEGELIUS, R. and KUNNAS, M. **Incidence of anaemia in a Finnish children's hospital.** *Ann. Paediat. Fenn.*, 1954–55, **1,** 166–170. [Child. Clin., Univ. Helsinki.]

In one year anaemia was diagnosed in 306 children, 6·5 per cent. of those admitted to hospital. In 44 per cent. of cases it was independent of other disease ; in 58 per cent. it was associated with acute infection. When infection had been of short duration and the anaemia was present on admission the anaemia was regarded as a primary condition. Of the primary anaemias all except 2 were of Fe-deficiency type.—F. C. Aitken.

1126

KIRSCHENFELD, J. J. and TEW, H. H. **Prevalence and significance of anemia as seen in a rural general practice.** *J. Amer. Med. Assoc.*, 1955, **158,** 807–811. [Fort Deposit, Ala.]

The criterion of anaemia was an Hb level below 11 g. and 12 g. per 100 ml. in women and men, respectively. Of 300 consecutive new patients 18 per cent. were anaemic. The anaemia was of Fe-deficiency type in 61 per cent. and of normochromic, normocytic type in 39 per cent. Principal causes of anaemia were pregnancy 24·1, inadequate diet 20·4, rheumatoid arthritis 18·5, acute and chronic infections 16·7 and excessive blood loss 11·1 per cent. of cases. Similar results were obtained when the study was extended to include 200 more patients.—F. C. Aitken.

SCHWARTZ, R., PHILLIPS, G. B., SEEGMILLER, J. E., GABUZDA, G. J. (Jr.) and DAVIDSON, C. S. **Dietary protein in the genesis of hepatic coma.** *New Engl. J. Med.*, 1954, **251,** 685–689. [Thorndike Mem. Lab., Boston City Hosp., Mass.]

The case of a patient with alcoholic cirrhosis is described in whom signs of impending coma were seen on 3 occasions when protein intake was raised from 50 to 75 g. daily. On each occasion protein restriction caused remission of the signs. Two cases of alcoholic cirrhosis are described in which high intake of protein may have had an adverse effect.—F. C. Aitken.

KALLAI, L. and CERLEK, S. Traitement des hépatopathies par un extrait de foie total. [**Treatment of liver diseases with an extract of whole liver.**] *Acta gastro-enterol. belg.*, 1955, **18,** 603–619. [Clin. Med., Univ. Zagreb.] Dutch, English and German summaries.

Ripason, a whole liver extract, was given in doses up to 5 ml. by vein daily for 8 to 12 weeks to 40 patients in hospital with chronic liver disease and receiving a high-protein, high-carbohydrate diet. Improvement was judged subjectively and on gain of weight, decrease of the size of the liver, improvement of liver function tests and disappearance of ascites if present and, when biopsies were performed, on the histological changes in the liver.

There was improvement in 26 of the patients; in 14 of them, including 5 with chronic hepatitis and 5 with compensated cirrhosis and all 3 with fatty degeneration, the results were excellent; in 12, including 4 with chronic hepatitis and 7 with compensated cirrhosis, they were good. In 11 patients, including 6 with compensated cirrhosis, there was no improvement, and of 7 with decompensated cirrhosis, 3 died. Myocarditis was present in 3; their electrocardiograms returned to normal under treatment. Histological examination showed improvement after treatment of chronic hepatitis, compensated cirrhosis and fatty degeneration; periportal and intralobular infiltration decreased or disappeared and fatty infiltration also disappeared, but in decompensated cirrhosis the more advanced changes were not altered.

1142

CHALMERS, T. C., ECKHARDT, R. D., REYNOLDS, W. E., CIGARROA, J. G. (Jr.), DEANE, N., REIFENSTEIN, R. W., SMITH, C. W. and DAVIDSON, C. S. (with MALONEY, M. A., BONNEL, M., NIIYA, M., STANG, A. and O'BRIEN, A. M.) **The treatment of acute infectious hepatitis. Controlled studies of the effects of diet, rest, and physical reconditioning on the acute course of the disease and on the incidence of relapses and residual abnormalities.** *J. Clin. Invest.*, 1955, **34,** 1163–1235. [Thorndike Mem. Lab., Boston City Hosp., Mass.]

All the 450 patients were male members of the United States armed forces, the course of whose illness was strictly defined and on whom comprehensive clinical observation and liver function tests were made regularly; the criterion of normality was a value 99 per cent. of that obtained in liver function tests on 279 "normal" soldiers stationed in Japan.

In the first study, with 260 patients, several analyses were made of the effects of diet and rest on the duration of the acute illness. The removal of 7 of the subjects which was later thought necessary did not affect the results. Patients who were allowed out of bed at will but who were confined to a hospital ward had a slightly shorter duration of illness than those kept strictly at rest in bed. Patients forced to eat a diet with a minimum of 3000 Cal. and 150 g. of protein and supplemented with choline and Multivitamin capsules had an illness 6 days or 22 per cent. shorter than others allowed the regular hospital diet to appetite; this difference was highly significant. There was no relation between the effects of diet and those of rest on the duration of illness.

In the second study of 200 patients, of whom 11 were removed during its course, analyses were made of the effects of intakes of energy and protein and of supplements of choline and vitamins on the duration of the disease. Patients given throughout their illness a diet with 19 per cent. of calories as protein had a mean duration of illness 14 per cent. shorter than patients given a diet with 11 per cent. calories as protein. For those on a diet with 4000 Cal. duration of illness was no shorter than in those on a diet of 3000 Cal. Patients given supplements of choline and a Multivitamin preparation did not have a shorter illness than patients who were given placebos. There was no demonstrable interaction among the 3 dietary components.

In 88 patients there was no evidence that strenuous exercise early in convalescence might precipitate a clinical relapse of infectious hepatitis.

In the fourth study 188 patients were selected at random from the original 450 for re-examination about 1 year after their initial treatment. Although there was no difference between patients in the first study who were forced to eat a nutritious diet and those who ate only as much as they desired, the repeat study indicated that in patients who received the high-protein, high-calorie diet in the second study the incidence of mild residual abnormalities was slightly higher than in the group on a normal diet.—G. F. Garton.

TASELAAR, J. A. Dystrophia musculorum progressiva; het effect van hormonale behandeling. [**Progressive muscular dystrophy; the effect of hormone treatment.**] *Nederland. Tijdschr. Geneesk.*, 1955, **99,** 2496–2499. [Acad. Ziekenhuis, Leyden.] English summary.

Twenty male patients with progressive muscular dystrophy were studied. Graphs are given showing the amounts of creatine and creatinine excreted by 8 patients of different ages, who had diets successively rich and poor in protein, combined with injections of vitamin B_{12} or di*iso*propylfluorophosphate or testosterone propylpropionate. None of these preparations caused creatine excretion to fall; it rose with an increase of protein in the diet. The testosterone derivatives improved the general condition of the patients and prevented further deterioration of the muscles. There was no relation between general condition and amount of creatine excreted.—M. Eddison.

1151

OJI, K., IKEGAWA, K., IMOTO, S. and YOSHIDA, T. **Treatment of muscular atrophies with amino acid mixtures.** *Med. J. Osaka Univ.* (*Engl. Ed.*), 1955, **6,** 291–308. [1. Dept. Int. Med., Med. Sch., Univ. Osaka.]

A mixture of 100 to 200 ml. of 5 per cent. enzymic hydrolysate of casein, 20 to 40 ml. of 2 per cent. DL-methionine, 20 to 40 ml. of 10 per cent. glycine and 40 ml. of 20 per cent. glucose solution was given intravenously at the rate of 60 drops per min. to 8 adult and 5 infant patients with progressive muscular dystrophy, 4 patients with neural muscular atrophy and 6 with amyotrophic lateral sclerosis. This treatment daily for from 3 to 12 weeks was found to be more effective in adults than in children and in patients treated soon after the onset of disease; it was most effective in muscular dystrophy. It gave rise to increases in limb circumference, muscular strength and bodyweight and to an improved sense of well-being. Abnormalities in chronaxie disappeared as a result of the treatment. Two types of response in creatine excretion to treatment were seen, one showing an immediate reduction and the other an increase 2 weeks after the treatment. Creatinine metabolism also was improved. Abnormalities in carbohydrate and protein metabolism were corrected by the treatment; the recovery was greatest in patients with muscular dystrophy. Creatine tolerance was increased significantly in patients treated with casein hydrolysate and added methionine and glycine over that in patients treated without additional glycine.—G. F. Garton.

6. FEEDING OF ANIMALS

GENERAL, INCLUDING DIGESTIBILITY TRIALS

1156

CLAWSON, A. J., REID, J. T., SHEFFY, B. E. and WILLMAN, J. P. **Use of chromium oxide in digestion studies with swine.** *J. Animal Sci.*, 1955, **14,** 700–709. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

In a trial with 10 groups of 8 pigs, 5 different rations, all containing 0·5 per cent. chromium oxide, were used. The pigs were fed free choice. Digestibility of the dry matter was estimated from samples collected over 24 hr., grab samples taken at 6 a.m. and 5 p.m., and in addition pooled samples taken at 5.30 a.m., 10.30 a.m., 3.30 p.m. and 8.30 p.m., and the results were compared with those obtained by the conventional method of 7-day collection periods.

It was first demonstrated that excretion of Cr_2O_3 reaches equilibrium with that in the feed 3 to 4 days after it is first given. The results by all methods were in close agreement. The most accurate was by 24-hr. collections, followed by 4 daily samples. For constituents of the ration which were highly digestible the coefficients of digestibility found by the Cr_2O_3 methods were nearer to those found by the conventional method than for the less digestible constituents.

Weight increases and efficiency of feed conversion were not affected by the inclusion of 0·5 per cent. Cr_2O_3 in the ration. Wide variation was found in the digestion coefficients between individual pigs on the same ration, but this was not related to the individual weight gain or efficiency.

T. D. Bell.

1157

FONTENOT, J. P., GALLUP, W. D. and NELSON, A. B. **Effect of added carbohydrate on the utilization by steers of nitrogen in wintering rations.** *J. Animal Sci.*, 1955, **14,** 807–817. [Dept. Animal Husb., Oklahoma Agric. Exp. Stat., Stillwater.]

Rations of hay, maize and minerals with 8, 10 and 12 per cent. protein were used in 3 digestibility and N balance trials with bullocks. To the low-protein ration carbohydrate was added as 350, 700 and 1050 g. cerelose and to the other 2 rations as 700 and 1050 g.

On the low-protein ration N retention was progressively depressed by increasing amounts of cerelose. The apparent digestibility of all constituents except N-free extract was reduced. In the rations with 10 and 12 per cent. protein, N retention was increased by addition of cerelose, and the apparent digestibility of crude protein and crude fibre was reduced, but that of organic matter was not affected, and that of N-free extract was increased. At all levels of protein the biological value of the N increased progressively with increasing cerelose.—T. D. Bell.

1158

SULLIVAN, J. T. **Cellulose and lignin in forage grasses and their digestion coefficients.** *J. Animal Sci.*, 1955, **14,** 710–717. [U.S. Reg. Pasture Res. Lab., Field Crops Res. Branch, U.S. Dept. Agric., State College, Pa.]

Cellulose and lignin in 36 samples of grass and one each of alfalfa and ladino clover were estimated, and the percentage digestibilities were estimated with sheep. Digestibility of cellulose was higher than was found for crude fibre in previous investigations of the same samples (Absts. 4385, Vol. 20; 2983, Vol. 22). The variation between samples was also as great as that of crude fibre. The percentage of cellulose was sometimes higher, sometimes lower than that of crude fibre. The digestibility of lignin was very variable, sometimes greater than 10 per cent. There was a significant correlation between percentage lignin and digestibility coefficient of cellulose and of dry matter. Further improvement in the method of estimating lignin is necessary before there would be any advantage in analysing grasses for cellulose or lignin or both instead of crude fibre.

T. D. Bell.

1159

NELSON, A. B., MACVICAR, R. W., ARCHER, W. (Jr.) and MEISKE, J. C. **Effect of a high salt intake on the digestibility of ration constituents and on nitrogen, sodium, and chloride retention by steers and wethers.** *J. Animal Sci.*, 1955, **14,** 825–830. [Dept. Animal Husb., Oklahoma Agric. Exp. Stat., Stillwater.]

In 2 trials with 4 bullocks the digestibility of the nutrients was not significantly affected by high salt intake. In 2 further trials with 6 wethers the digestibility of organic matter and N-free extract was reduced by high salt intake. N retention decreased slightly and sodium and chloride retention increased significantly in both species on high salt intake.—J. C. Gill.

1160

DIJKSTRA, N. D. and BRANDSMA, S. Over de verteerbaarheid en voederwaarde van verse lucerne. [**Research on the digestibility and feeding value of fresh lucerne.**] *Versl. Landbouwk. Onderzoek.*, 1955, No. 61.5, pp. 19. English summary.

Tests were made with first-cut lucerne at Hoorn, from a field in the Wieringermeerpolder, both cut in May and June 1954, and from a field at Wijdenes (North Holland) cut in May 1951, and a late cut from the Hoorn field in September 1953.

Digestible nutrients and feeding value decreased rapidly with age of the lucerne. Tables and graphs show the relations between crude and true protein, crude protein and fibre, crude fibre and starch equivalent, true protein and digestible true protein, and they are also expressed as equations.

I. Leitch.

1161

LLOYD, L. E. and CRAMPTON, E. W. **The apparent digestibility of the crude protein of the pig ration as a function of its crude protein and crude fiber content.** *J. Animal Sci.*, 1955, **14,** 693–699. [Dept. Nutrit., Macdonald Coll., McGill Univ., Que.]

In digestibility trials with pigs of about 90 lb. liveweight rations of maize alone and with malt sprouts, linseed oilmeal, wheat bran or maize starch and oat groats were used. The rations were designed to give different levels of protein and of crude fibre. Statistical analysis of the results showed that the percentage crude fibre and the percentage protein in the ration affected the percentage digestibility of the protein equally.

T. D. Bell.

1162

CRAMPTON, E. W., MACKAY, V. G. and LLOYD, L. E. **The biological value of the protein and the apparent digestibility of the crude fiber of malt sprouts.** *J. Animal Sci.*, 1955, **14,** 688–692. [Dept. Nutrit., Macdonald Coll., McGill Univ., Que.]

Digestibility trials were made with pigs of about 90 lb. liveweight to compare the protein of linseed oilmeal and malt sprouts and the fibre of wheat bran and malt sprouts. When 45 per cent. of the protein of the ration was supplied by malt sprouts or linseed oilmeal, the former had only 84 per cent. of the value of the latter. When only 27 per cent. of the protein was so supplied, the 2 were about equal. The digestibility of the fibre was only 8 per cent., compared with 20 per cent. for wheat bran. This was thought to be the reason for the low apparent digestibility of the protein of malt sprouts.—T. D. Bell.

1163

ERIKSSON, S. **Digestibility and metabolizable energy of poultry rations at different levels of nutrition.** *Acta Agric. scand.*, 1955, **5,** 201–214.

In 72 experiments with laying hens the digestibility and the metabolisable energy of 2 feeds, each given at high, medium and low levels, were estimated. It was shown that only the digestibility of protein was affected by the level of feeding, increasing at the higher levels. When corrections were made for the constant amount of metabolic nitrogen in the faeces, these differences in digestibility of protein were eliminated. The method of estimating crude fibre in the faeces is not standardised, and this causes discrepancies in estimations of digestibility. Since this coefficient of digestibility is not essential for estimating the nutritive value of feeds for poultry it is considered better to estimate only the digestibility of total carbohydrates, and not divide them into N-free extract and crude fibre. The percentage of metabolisable energy was not affected by the level of feeding. Comparison of the amount of metabolisable energy found directly in the experiments with calculated values showed significant differences. Calculation from existing data is not recommended.—T. D. Bell.

1164

DIJKSTRA, N. D. De verteerbaarheid en voederwaarde van sorghumglutenvoer. [**Digestibility and feeding value of sorghum gluten feed.**] *Landbouwk. Tijdschr.*, 1955, **67,** 555–557. [Rijkslandbouwproefstat., Hoorn.] English summary.

Sorghum gluten feed, like maize gluten feed, is the dried residue from the manufacture of starch. Its digestibility was estimated in 10-day tests with 3 wethers. Composition and digestible nutrients per cent., to the nearest whole number, were as follows: moisture 12, crude protein 23, true protein 19, crude fat 5, N-free extract 53, crude fibre 4, ash 3; digestible crude protein 18 and digestible true protein 15. With the same "value" as for maize gluten feed, namely, 96, starch equivalent was computed to be 72.—I. Leitch.

1165

NOLAND, P. R., FORD, B. F. and RAY, M. L. **The use of ground chicken litter as a source of nitrogen for gestating-lactating ewes and fattening steers.** *J. Animal Sci.*, 1955, **14,** 860–865. [Univ. Arkansas Agric. Exp. Stat., Fayetteville.]

In feeding trials with 36 gestating-lactating ewes those given ground chicken litter to replace the normal protein concentrates performed as well as those getting soya bean meal. As a source of supplementary nitrogen ammoniated molasses was inferior to both these feeds. On equal feed intakes fattening bullocks given cottonseed meal made faster gains than those on ground chicken litter, but gains were similar when the feed intake of the latter was increased by 15 per cent. No digestive upset occurred in either trial.

J. C. Gill.

1166

ERIKSSON, S. Oxalsyrans halt i rotfruktsblast och dess betydelse i utfodringen. [**Oxalic acid content of root tops and its significance for animal feeding.**] *Kungl. Lantbruksakad. Tidskr.*, 1955, **94**, 111–118. English summary.

In 50 samples of root tops, sugar beet, fodder sugar beet and fodder beet contained on the average 7 per cent. of water-free oxalic acid in the dry matter. About half of this was soluble in water. Tops from swedes, turnips and marrow-stem kale contained no oxalic acid or only a trace.

After 3 wethers were given oxalic acid and its K salt, 12·5 per cent. of the dose was recovered in the faeces and urine. With 2 wethers receiving K and Ca oxalates it was calculated, assuming a destruction of soluble oxalate similar to that in the previous experiment, that 32 per cent. of the Ca oxalate had been destroyed during digestion.

A. Hepburn.

BRUNE, H. Experimentelle Untersuchungen am Wiederkäuer zur alimentären Wirksamkeit der nativen Oxalsäure. Beitrag zur Fehlernährung mit Zuckerrübenblatt, Rübenblattsilage, Trockenblatt, Troblako und Trockenschnitzel. 1. [**Experimental studies with the ruminant on the nutritional effects of naturally occurring oxalic acid. Contribution to explain the low nutritive value of sugar-beet leaves, beet leaf silage, dried leaves, Troblako and dried slices. 1.**] Beitrag zur Fehlernährung mit Zuckerrübenblatt, Rübenblattsilage, Trockenblatt, Troblako und Trockenschnitzel. 2. [**Contribution to explain the low nutritive value of sugar-beet leaves, beet leaf silage, dried leaves, Troblako and dried slices. 2.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10**, 102–122; 127; 147–192. [Inst. Tierphysiol. Tierernährung, Univ. Göttingen.]

1. A review of the literature on oxalic acid metabolism includes many references and occupies half the paper.

The experimental animals were six 2-year-old Leineschaf wethers and six 1- and 2-year-old Württemberger Landschaf wethers. They were kept in metabolism cages for experiments lasting 100 days, divided into 10-day periods. The control diet was meadow hay. Drinking water was distilled.

Two wethers were fed on fresh beet leaves for 14 days and were then killed. The rumen contained soluble oxalic acid, but the proximal part of the small intestine contained no soluble oxalic acid, nor did the faeces of the experimental animals. The percentage of the total oxalic acid of the feed recovered in the faeces varied with the feed, from 32 with fresh leaves to 80 with one kind of Troblako. The percentage recovered in the faeces was always high at the beginning of a study and then fell. With different diets there occurred positive or negative correlations between the percentage of oxalic acid recovered and the percentage of dry matter in the faeces.

2. Balances of total and water-soluble oxalic acid and Ca and of total Mg and P were studied in wethers given the different beet products alone or with Ca salts, potato starch or cellulose.

Less oxalic acid was recovered in the faeces than the difference between intakes of total and water-soluble oxalic acid. This is interpreted as a sign of microbial breakdown of insoluble calcium oxalate. Up to 50 per cent. of the insoluble oxalic acid intake failed to appear in the faeces. On the other hand, when the fodder was rich in water-soluble oxalic acid and contained excess Ca, insoluble oxalic acid in faeces might exceed that in fodder. $CaCO_3$ produced this effect more readily than $CaHPO_4$. When *bolus alba* was given no oxalic acid was found in the faeces, but oxalic acid excretion was increased by supplements of starch or cellulose. When digestibility of crude fibre, crude protein and N-free extract of the diet was low, oxalic acid excretion was high. This is considered to be related to low bacterial activity.

Even with a large excess of oxalic acid over Ca the wethers might be in positive Ca balance. It is concluded that Ca oxalate is available to the sheep. Ca balances were also sometimes negative in the presence of a large Ca excess. Ca retention was better with fresh than with dried beet leaves. Mg retention tended to parallel Ca retention, but the P balance was strongly dependent on the dry matter content of faeces.

When sheep received Ca salts with oxalate-rich fodders and drinking water to appetite they had a high output of urine which could not be traced either to high oxalic acid intake or high alkali intake.

In the first 10 days of feeding on dried beet leaves serum Ca and phosphatase always rose slightly, but later they tended to fall, though they remained within the limits of normal variation. Serum P showed some changes in the opposite direction.

It is concluded that the oxalic acid is not solely responsible for the poor results obtained from sugar-beet leaves used as fodder.—D. Duncan.

1168

JARL, F., NORDFELDT, S. and HELLBERG, A. Utfodringsförsök med ensilage framställt med användande av Reymersholms ensileringsfosfat. [**Feeding experiments with silage made with Reymersholm silage-phosphate.**] *Kungl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 109, 1955, pp. 15.

The making of silage with $NaH_5(PO_4)_2 . NaHSO_4$ and its quality were described in a report in 1954 (see Abst. 4238, Vol. 24). The results of feeding experiments are now briefly reported. Digestibility trials were made with 3 cows at one centre and at another with 4 wethers in which phosphate silage was compared with silage made with beet or molasses. Digestibility was good. Milk production tested with 4 groups each of 6 cows at the one centre and 3 groups of 6 at the other showed no difference in either yield or quality as compared with production on hay or other silages.

An account of the effect of phosphate silage on retention of P was published earlier (see Abst. 3887, Vol. 24). The effect on composition of the urine was tested with 3 cows with a mean yield of about 20 kg. milk daily. There was no effect on volume of urine. With increasing amounts of silage, 2·6, 5·1 and 9·7 kg. daily each for one week, Ca and P in urine increased and *p*H fell from 8·8 to 7·8.—I. Leitch.

1169

PACI, C. L'utilizzazione alimentare della paglia di riso. [**The use of rice straw in feeding.**] *Riv. Zootec.*, 1955, **28,** 215–218.

The rice straw available for feeding is generally not all used. After threshing it soon rots, since it is still green, with a high moisture content, and the harvest is too late in the year for drying by the sun. There is the added disadvantage that it has a very high ash content, 15 per cent. of the dry matter, and two-thirds of this is silica. When used as a roughage for livestock it has to be combined with 3 or 4 times its weight of clover or lucerne hay. The mixture is then comparable to meadow hay. Silage in experimental silos was made of rice straw with the addition of mineral acids. It was analysed after 98 days, with the following results : dry matter 31·20, crude protein 1·60, ether extract 0·59, crude fibre 11·37, N-free extract 12·59 and ash 5·05 per cent. The composition was almost the same as that of the straw before ensiling. The silage was of good colour and smell, with *p*H 3·8, and the ammonia N was only 4·4 per cent. of the total N. No feeding trial was made, but in view of the similarity in composition of silage and straw it is suggested that they could be used in the same way, with the same precautions.—T. D. Bell.

1170

FRENCH, M. H. **The feeding value of sweet potato tubers.** *East African Agric. J.*, 1955, **21,** 18–19. [Joint Animal Indust. Div. E.A.A.F.R.O., E.A.V.R.O.]

Sweet potatoes, purchased from African producers, had the following percentage composition on a dry matter basis : crude protein 5·13, ether extract 1·08, crude fibre 2·30, N-free extract 87·53, ash 3·46, SiO_2 0·36. They were slightly higher in protein and lower in fibre than cassava or edible canna. The average percentage digestibilities of the constituents, obtained with sheep, were : crude protein 37·5, ether extract 51·6, fibre 79·3, N-free extract 95·5, dry matter 85·9, organic matter 92·0.

[**Feeding value of Giessen radish, Sarepta mustard var. 40/44 and Giessen variegated vetch.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 134–146. [Agrik. Chem. Inst., Justus Liebig Hochsch., Univ. Giessen.]

Digestibility trials were made with wethers on these 3 new fodder plants, given green or as hay.

As green fodder the vetch contained most digestible crude protein, 18·58 per cent. on a dry matter basis ; the other 2 plants had 14·21 and 14·55 per cent. In hay there was little difference in digestible crude protein between them. The vetch when green had the highest starch equivalent, but as hay the mustard was highest. All had about 90 per cent. dry matter as hay. All were readily accepted by the sheep. The digestibility of all the organic constituents, but especially of fibre, was highest in Sarepta mustard hay, which was comparable to very good meadow hay, while the other species were comparable to good meadow hay.

[**Animal husbandry in French West Africa: its economic and social importance. Conditions for its development and improvement.**] *Rev. Élevage Méd. vét. Pays trop.*, 1955, **8,** 137–162.

In French West Africa two-thirds of the territory is engaged in animal husbandry, and two-thirds of the animals are in the northern part. Limited rainfall with long dry periods over large areas, and disease which periodically decimates the flocks and herds, prevent the full development

of the animal industry. The ignorance of the people retards progress also.

A programme has been initiated to improve conditions. The first aim has been to improve animal health, and concurrently water supplies have been improved by deep borings, erection of tanks, pumping from deep wells and controlling streams and lakes. Meanwhile investigations are in progress on the possibilities of pasture improvement, and experimental farms for stock improvement by breeding and crossing are being established. Movement and marketing of livestock, meat, milk and hides are being controlled and assisted. The organisation and its progress to date are described.

MAGIDOV, G. Kukuruza—tsennaya kormovaya kul'tura dlya loshadei. [**Maize—a valuable fodder crop for horses.**] *Konevodstvo*, 1955, **25**, No. 5, 31–34.

To obtain good results from giving maize to horses it should be accompanied by fodder rich in protein, such as legume hay, bran and oats. Although maize is a valuable feed, its nutrient value being almost 30 per cent. higher than that of oats, its ash content is low, the amount of Ca in maize being only 0·03 per cent., 1/4 of that in oats. The addition of legume hay not only balances the ration with respect to protein but also compensates for the deficiency of Ca. Maize is highly digestible, horses being able to digest up to 90 per cent. of the organic matter. The yellow varieties of maize contain considerable amounts of carotene, up to 9 mg. per kg. If the ration is properly balanced with respect to protein and ash, horses can be given 15 per cent. less maize than oats. Maize should not be moistened or steamed before feeding, as if this is done it ferments rapidly in the horse's stomach.

If maize is given as silage it should replace about half the hay ration. Silage from maize harvested at the milk stage contains 80 mg. carotene per kg.

KOCH, R. M., SCHLEICHER, E. W. and ARTHAUD, V. H. **Weight changes in beef calves following birth.** *J. Animal Sci.*, 1955, **14,** 792–796. [Univ. Nebraska, Lincoln.]

Weights of 218 calves were measured at birth and at 12- or 24-hr. intervals for the 72 hr. after birth. It was shown that during the first, second and third 24-hr. period the average gain was 1·2, 1·5 and 1·8 lb., respectively. The average gain in the first 3 days was the same as the average daily gain from birth to weaning. The variation in one calf within the period when birthweights are normally taken was small compared with the variation between calves. It did not seem to be of practical importance to make adjustments for the differences in times of weighing which inevitably occur in practice.—T. D. Bell.

1182

VOLCANI, R. and EYAL, E. **Rearing calves on limited milk rations.** *Ktavim, Rec. Agric. Res. Stat. Rehovoth,* 1953, **4,** 23–24.

In 2 sets of experiments the effect of rearing calves with limited amounts of milk was studied. In the first series rations of 160 litres whole milk were given in 45 days, and concentrates were allowed to appetite. The growth and health of the calves getting this treatment were not inferior to those of calves on the usual ration of 380 litres milk, and their first lactation performances compared favourably with those of their dams.

In the second set of experiments groups of calves were reared on different combinations of full and reconstituted dried skimmed milk over periods of 25 to 49 days and a control group got 380 litres full milk in 75 days. There was no advantage in giving 100 litres skimmed milk to calves that got 100 litres full milk and concentrates. All the calves on the limited milk rations gained less weight during the first 3 months than those on full milk, but the difference in weight was eliminated during the next month. Consumption of concentrate was greater in the groups getting limited quantities of milk, and in all groups the intake and efficiency of utilisation of total digestible nutrients was the same. From both experiments it is concluded that restricted milk rations given during a short period can be used satisfactorily for rearing calves.—T. D. Bell.

1183

LAMPKIN, G. H. and PARKIN, S. I. J. **Calves reared at grass.** *Agriculture, J. Minist. Agric. Engl.*, 1955, **62,** 255–257. [Animal Breeding Res. Organiz., Cold Norton Farm, Stone, Staffs.]

In trials in 2 years calves were purchased when 1 week old, between April and July, and were kept outdoors on pasture day and night until October. They were given whole milk until 4 weeks old, 21 gal. altogether, and then a milk substitute, 44 gal., until weaning at 12 weeks old. A concentrate, on a scale based on size, rising to a maximum of $2\frac{3}{4}$ lb. at 266 lb. liveweight, was also given. The calves gained on the average 10·2 lb. per week each. Similar calves reared indoors and getting hay and silage to appetite instead of pasture gained 7·2 lb. per week. All calves remained in good health, and examination of faeces did not show any excessive parasitic infestation due to rearing the young calves on pasture.—T. D. Bell.

1184

HANCOCK, J. and PAYNE, W. **The direct effect of tropical climate on the performance of European-type cattle. 1. Growth.** *Empire J. Exp. Agric.*, 1955, **23,** 55–74. [Ruakura Animal Res. Stat., Animal Res. Div., Dept. Agric., N.Z.]

Eight sets of identical twins of predominantly Jersey type were used. All twin sets were born and uniformly reared to $7\frac{1}{2}$ months of age in New Zealand. At this stage one member of each set was shipped to the Sigatoka region of Fiji. Feeding and management in the 2 countries were identical, the only difference being climate. Liveweights and body measurements were recorded from $7\frac{1}{2}$ months to 2 years of age.

The Fiji twins lost weight during transit and quarantine, but recovery was rapid during the ensuing months. Growth rates and feed intakes fell during periods of high temperature. As a result maximum weight differences at calving were on the average 84 lb. Body measurements except belly girth were correspondingly reduced. The belly girths of the Fiji twins tended at certain times to be higher than those of their New Zealand mates. This was attributed to drinking more water. Differences in bodyweights and measurements were much less by the end of the first lactation. In view of the small within-set differences at the end of the first lactation it was concluded that the stunted appearance of cattle of European type reared in Fiji is due largely to poor nutrition or management or both and not to climate. Between-set differences in adaptability to environment showed that selection for tropical conditions might be worth while.—J. N. Aitken.

AMSCHLER, J. W., BAUMGARTNER, F. and PAMMER, H. Die Aufzucht von Braunviehkälbern mit Aurofac-2A. [**Rearing Brown calves with Aurofac-2A.**] *Bodenkultur*, 1954, **8**, 34–38. [Inst. Tierzucht, Hochsch. Bodenkultur, Vienna.]

For the first 6 weeks of life 5 Brown autumn calves had Aurofac-2A in their milk, 0·3 g., supplying 2·4 mg. aureomycin per kg. milk, and 4 had none. Both groups had hay from the third week and concentrates [details given] from the fourth.

Mean daily weight gain was almost 50 per cent. greater in the aureomycin group; per kg. gain they consumed whole milk 8·027 kg., concentrates 76 g. and hay 102 g., supplying 276·6 g. digestible protein in 1·263 kg. starch equivalent, as against 11·772 kg., 114 g. and 151 g., supplying 405·9 g. digestible protein in 1·856 kg. starch equivalent, for the controls. The calves given aureomycin were all healthy and lively, whereas all but one of the controls scoured. The cost of the aureomycin supplement was 15·6 groschen per kg. weight gain or on the average 6·45 schilling per calf for the 6-week period.—W. M. Deans.

1186

OWEN, F. G., VOELKER, H. H., JACOBSON, N. L. and ALLEN, R. S. **The comparative effects of various antibiotics and an arsenical upon the growth, health, and certain blood constituents of dairy calves.** *J. Dairy Sci.*, 1955, **38**, 891–900. [Dept. Animal Husb., Iowa State Coll., Ames.]

Two experiments were made. In the first, 3 groups of 8 Holstein calves receiving terramycin or penicillin were compared with a control unsupplemented group. In the second, terramycin, bacitracin, chloromycetin and 3-nitro-4-hydroxyphenylarsonic acid were given. All calves received whole milk for the first 2 weeks and a milk replacement of dried whey reconstituted with water during the first 7 weeks. A calf starter of ground maize, ground oats and soya bean oilmeal was supplied from the 7th to the 12th week. The antibiotics were given at the rate of 40 mg. daily in the milk replacement and at 80 mg. daily in the calf starter. The arsenical was given at the rate of 30 mg. daily during the first 6 weeks and thereafter at 30 mg. per lb. starter.

In experiment 1 the rates of gain of the calves getting aureomycin and terramycin were significantly higher than those of the controls. The gains of the penicillin group were on the average 14 per cent. less than those of the controls. In experiment 2 the gains of all the treated calves were significantly higher than those of the controls. When the antibiotics and arsenical were withdrawn the rates of gain of the penicillin and control groups exceeded those of the other groups. Treatments which stimulated growth also improved efficiency of feed conversion. There was no effect of treatment on erythrocyte, total leucocyte, or differential leucocyte count. Hb, plasma fat and faecal *p*H were not affected by any of the treatments.—J. N. Aitken.

1187

LASSITER, C. A., DENTON, T. W. and RUST, J. W. **The evaluation of an unidentified growth factor and terramycin for young dairy calves.** *J. Animal Sci.*, 1955, **14**, 769–774. [Dairy Sect., Univ. Kentucky, Lexington.]

Thirty-two Jersey and Holstein calves were reared on whole milk, a calf-starter and hay from 2 to 86 days of age. Experimental groups were given, in addition to this basal ration, supplements of crystalline terramycin or a mixture of products from the fermentation of terramycin and streptomycin, or both. The mixture of fermentation products was used as a source of unidentified growth factor. The rations received by all groups were the same in proximate composition, except that the percentage ash when the source of unidentified growth factor was included was higher than in the other rations.

The addition of the supplements did not improve growth rate or efficiency of feed utilisation. Terramycin tended to reduce scouring, and the source of unidentified growth factor to increase it. The latter effect may have been due to the higher ash content.—T. D. Bell.

1188

LASSITER, C. A., DENTON, T. W. and RUST, J. W. **The effects of chlortetracycline and ethomid C/15 on growth, apparent digestibility and blood levels of urea and total non-protein nitrogen in young dairy calves.** *J. Animal Sci.*, 1955, **14**, 760–768. [Univ. Kentucky, Lexington.]

An experiment was made with 18 male Holstein and Jersey calves reared from 2 to 86 days of age on limited milk and concentrates and hay to appetite. The effect was studied of supplements of chlortetracycline and a surface-active agent, Ethomid C/15, (polyoxyethylene cocoamide) on growth rate, efficiency of feed utilisation, scouring, digestibility of nutrients and levels of blood urea and N.P.N.

Both supplements improved growth rate, and the antibiotic was better than the surface-active agent. The chlortetracycline also improved efficiency and reduced scouring. There was no effect on the digestibility of the nutrients or the level of blood urea. Chlortetracycline reduced blood N.P.N. during the first 7 weeks, the period during which growth was stimulated most.—T. D. Bell.

1189

HIESS, H. Praktische Erfahrungen in der Baby-Beef-Mast. [**Practical experience in fattening for baby beef.**] *Bodenkultur*, 1954, **8**, 77–80. [Versuchswirtschaft, Hochsch. Bodenkultur, Vienna, Gr. Enzersdorf.]

The system of indoor rearing of selected dairy calves to from 400 to 500 kg. liveweight at 15 months for baby beef, begun in 1948 as a subsidiary enterprise in connection with the dairy herd at the college farm, is described in detail. Weights at 3-month intervals are tabulated for 12 male and 9 female calves of different breeds and crosses, and the amounts of the different feeds consumed are also given. Male calves did better than female ; crosses did not do better than purebred. Emphasis is laid on uniformity of feeding, to maintain unchecked growth and minimise labour. For this reason no green feed is given. Whole milk rises from 5 litres daily in the first week to 9 in the eighth and then falls by 1 litre each week until it ceases at the end of the sixteenth week. The calves are gradually introduced to other feeds, mainly silage of beet leaves, wet slices, maize or vetch and rye ; dried slices and alfalfa hay are also given. The only concentrates used are groundnut meal, rapeseed meal and wheat bran. Costs are kept down by the use of homegrown feeds.—W. M. Deans.

1190

WINCHESTER, C. F. and HOWE, P. E. **Relative effects of continuous and interrupted growth on beef steers.** *U.S. Dept. Agric. Tech. Bull.* No. 1108, March 1955, pp. 34.

The animals used were 5 pairs of identical twin purebred Aberdeen-Angus steers and 1 pair of Hereford × Guernsey crossbreds. The pairs were split so that one member of each set was given the control ration with a liberal energy content. The remaining 6 co-twins were divided into 3 groups of 2 animals each and given rations containing 50, 62 or 75 per cent. of the energy content of the control ration. Restricted feeding of the animals on the 50 and 62 per cent. rations was begun at 6 months of age ; at 12 months they were again given liberal rations. Of the 2 animals on the 75 per cent. energy ration 1 was restricted at 6 months and the other at 7 months. This ration was given in one case for 10 months and in the other for 8 months. After the period of restriction all animals were fed to appetite. Bodyweights and measurements were recorded. The animals were slaughtered when they reached a weight of 1000 lb.

At the lowest levels of intake there was little or no gain in bodyweight although development in terms of some skeletal measurements continued at a reduced rate. After the period of restriction weight gains were rapid and economical. The retarded animals required 10 to 20 weeks more to finish. At slaughter there was no difference between control and experimental animals in either carcase grade or meat quality. It is concluded that during periods of feed scarcity animals may be maintained at maintenance levels without serious consequences.—J. N. Aitken.

1191

MORRISON, J., SMYTH, W. G., HALE, R. W. and BROWN, W. O. **Fattening of cattle: a comparison of indoor winter fattening with summer fattening on grass.** *Res. and Exp. Rec. Minist. Agric. N. Ireland*, 1952–53 (1955), **3**, 90–97. [Agric. Res. Inst., Hillsborough.]

In a trial with 16 bullocks of Shorthorn type purchased in the autumn, a group of 5 was fattened indoors on silage, a similar group was fattened indoors on silage plus hammer-milled oat sheaves and hay, and the remaining 6 were maintained outdoors during the winter on silage, straw and surplus swedes and then fattened on grass in the summer. The average initial weight of the bullocks was 9½ cwt. The fattening of groups 1 and 2 began on 16 December, group 1 finishing on 2 March and group 2 taking a fortnight longer to attain the same weight. The daily liveweight increases were 2·40 and 1·85 lb. Group 3 was fattened from 26 March to 6 July, with a daily liveweight increase of 2·43 lb.

All the bullocks graded well at slaughter. The costs and returns were estimated, showing the highest profit from group 3, followed by group 1. It should not be considered from these results that winter fattening must be abandoned. Before such a decision is made, availability of grassland and accommodation, and the desirability of keeping meat supplies steady through the year, must be considered.—T. D. Bell.

1192

MORRISON, J., STEPHENSON, W. A., HALE, R. W. and BROWN, W. O. **Winter fattening of bullocks: grass silage compared with arable crop silage.** *Res. and Exp. Rec. Minist. Agric. N. Ireland*, 1952–53 (1955), **3**, 98–105. [Agric. Res. Inst., Hillsborough.]

Silage of peas and oats, dry matter 17·8 per cent. and crude protein 15·5 per cent. of dry matter, was compared with grass silage, dry matter 21·0 per cent. and crude protein 13·9 per cent. of dry matter, for fattening bullocks indoors in winter. There were 2 groups of 5 bullocks of initial liveweight about 9 cwt. They were given 6 lb. bruised oats and good quality hay to appetite and 70 lb. of one or other of the silages daily. The fattening period was from 5 February to 5 May, and the grass silage group gained 2·0 lb. per head daily during this period. The rate of gain of the

other silage group was 1·3 lb. daily. At slaughter the group on pea and oat silage did not grade as well as the grass silage group. The financial results showed that the use of silage of crops on arable land was unprofitable; the grass silage was very satisfactory.—T. D. Bell.

1193

HUEY, J. B. D. **A comparison of the feeding value of grass and arable crop silages for store and fattening cattle.** *Res. and Exp. Rec. Minist. Agric. N. Ireland*, 1952–53 (1955), **3**, 130–141. [Loughry Agric. Coll., Cookstown, Co. Tyrone.]

This experiment was made during 2 successive winter periods. One group of 4 yearling Dairy Shorthorn steers and another of 4 yearling heifers were fed entirely on grass silage. Two similar groups received silage of arable crops. During the intervening summer all animals were at pasture. The arable crop was a mixture of oats and peas and the silage contained 20·35 and 16·16 per cent. dry matter in the 2 periods. The crude protein content of the dry matter was 16·22 and 14·43 per cent., respectively. The grass silages had 20·25 and 18·2 per cent. dry matter and 12·59 and 15·03 per cent. crude protein.

In both winters the steers and heifers on grass silage made substantially greater liveweight gains than those on oat and pea silage. Total silage and dry matter consumption were also greater in the grass silage groups. Liveweight gains were closely related to dry matter consumption. The poor results obtained with the oat and pea silage were partly due to the fact that it was less palatable. Where good grass can be grown, grass silage will be of more value than silage of other green crops.—J. N. Aitken.

1194

GERLAUGH, P., KLOSTERMAN, E. W. and KUNKLE, L. E. **The relative value of three grades of feeder steers when wintered, grazed and fed grain on pasture.** *Ohio Agric. Exp. Stat. Res. Circular* No. 26, September 1954, pp. 10.

In each of 2 successive years 3 groups of 20 steers were selected to represent choice, medium and common grades. In both years the choice steers were Herefords, the medium Shorthorns, and the common Holsteins. All animals were wintered on maize silage, mixed hay and soya bean oilmeal. Grazing was begun in April in each year. Maize was given during the latter part of the summer. There was little difference between the groups during the wintering and early grazing phases of the experiments. The liveweight gains of the Holsteins were greater than those of either the Herefords or Shorthorns when grain was given on pasture. Under the conditions of this experiment the poorer grades proved to be the most profitable, because of the greater margin between purchase and selling price.—J. N. Aitken.

1195

KIRSCH, W. Grundsätzliches zur Fleischgewinnung über das Rind unter besonderer Berücksichtigung der Kälber- und Jungrindermast. [**Principles of meat production from cattle with special reference to the fattening of calves and young cattle.**] *Züchtungskunde*, 1955, **27**, 56–63. [Inst. Tierzuchtlehre, Landwirtsch. Hochsch., Hohenheim.]

From experiments on fattening young animals and studies of market statistics it is concluded that there is no need to change the predominant dual-purpose types of German cattle, but breeders and others should concentrate on extending the milking life of cows.

The best results in practice come from all kinds of milk fattening and with autumn calves started on good pasture. Fattening of young bulls should be considered only under such conditions and with good pasture management and no stall feeding. Spring calves may be successfully fattened where there are plenty of cheap by-products, such as sugar beet products. The practical possibilities for baby beef production are still unknown.

1197

SANDAL, P. C. and GAREY, C. L. **Effect of top-dressing pastures with superphosphate on beef yields and distribution of available P_2O_5 in the soil.** *Agronom. J.*, 1955, **47**, 229–231. [Univ. Arkansas, Fayetteville.]

Trials were made on a gravelly silt-loam bearing a pasture of Bermuda grass and legumes. Compared with the control pastures (not topdressed) which produced 61 lb. beef per acre in a year, those which had received 200 lb. of 20 per cent. superphosphate per acre annually for 6 years had considerably higher available P_2O_5 contents in the first 3 in. of soil, but little more between 3 and 6 in. These pastures produced 275 lb. beef per acre. Where topdressing had been at the rate of 600 lb. per acre annually, 382 lb. beef per acre were

obtained. The soil had the greatest amounts of available P_2O_5 at all depths up to 6 in. Soil organic matter and also soil stability were increased almost in proportion to the amount of P_2O_5 applied. It is stated that observations showed that this could be accounted for by increasing growth of the pasture.—J. L. Corbett.

1198

WOODWARD, R. R., QUESENBERRY, J. R. and WILLSON, F. S. **Production and carcass quality in beef cattle.** *Montana Agric. Exp. Stat. Circular* No. 207, December 1954, pp. 11.

The effect on carcase quality of selection for heavier weaning weights and rate and efficiency of gains was studied. Weight, rate and efficiency of gain and carcase records of 635 Hereford steers were analysed. The animals were weaned at 6 months of age and then fattened for 250 days before slaughter. They were reared under typical range conditions.

Birthweight was positively related to weaning weight, final weight and rate of gain, but not to carcase grade. There was no correlation between weaning weight and carcase grade, so that selection for heavier weaning weight did not prejudice the quality of the carcase. Faster gains produced carcases of higher grade, and efficiency and rate of gain were closely and positively correlated. Grading the live animals before slaughter gave a fairly good indication of carcase grade, but was more accurate in the prediction of the thickness of the external fat measured over the eye muscle than of the area of lean of the eye muscle. Selection for rate of gain would not necessarily result in improved conformation, or vice versa, since fleshing quality and rate of gain were not correlated. On the other hand, these 2 characteristics were not antagonistic, and selection for each separately could be made.—T. D. Bell.

MILK PRODUCTION

1200

PERUCHON DE BROCHARD, J. Revision des formules types modernes alimentaires pour vaches laitières. **[Revision of typical modern feed formulae for dairy cows.]** *Rev. d'Oka*, 1955, **29,** 74–77.

Giving too much protein to dairy cows may do more harm than good. A table of suggested scales and proportions of total feed expressed in feed units and protein are presented for cows from 300 to 650 kg. liveweight giving 10 litres milk of from 3 to 6 per cent. butterfat. The ratio of the dry matter of feed to its value in feed units is important and should be as narrow as possible.—T. D. Bell.

1201

KRÜGER, L. and MÜLLER, W. Über Futteraufnahme und Verzehrleistungen bei Milchkühen. 1. Eine theoretische Betrachtung zum Problem der Sättigung. **[Feed intake and consumption in milk cows. 1. Theoretical consideration of the problem of satiety.]** *Züchtungskunde*, 1955, **27,** 17–37. [Inst. Tierzucht, Justus Liebig Hochsch., Giessen.]

The theoretical discussion is based on 58 references. It is suggested that the feeling of satiety in cattle is controlled primarly by the filling of the reticulo-rumen, and that this in turn depends on the volume of the organ, the time the feed remains in it and the sp. gr. of the feed. The sp. gr. of the feed can be estimated by pyknometer which is described, and the time spent by the feed in the reticulo-rumen is estimated from the total transit time on the assumption that transit time from omasum to rectum is constant. Estimation of the volume of the reticulo-rumen in the living animal is still to be considered. At the moment the animal's requirement for satiety is based empirically on the volume eaten.—D. Duncan.

1202

CONVERSE, H. T. **Calcium requirements of dairy cattle.** *U.S. Dept. Agric. Tech. Bull.* No. 1092, April 1954, pp. 25.

During a 20-year period 4 experiments were made with 51 animals in all. Successive attempts were made to deplete the cows by giving rations low in Ca. In some this was done during growth, pregnancy and subsequent lactation and in others during lactation only. The rations in 3 of the experiments consisted of timothy hays of low Ca content and a suitable grain mixture. In the fourth experiment calves were reared on a ration consisting of 2 to 3 lb. hay and a grain mixture containing only 0·078 per cent. Ca. The average Ca content of the ration was only 0·12 to 0·14 per cent. of the dry matter. The Ca content of the dry matter of the rations used in the other experiments ranged from 0·16 to 0·95 per cent. It was shown that a ration containing only 0·16 per cent. Ca was adequate for growth, pregnancy and lactation and a ration containing 0·14 per cent. Ca was adequate for growth but not for pregnancy. It is concluded that there was no justification for giving a Ca supplement with rations of grain and timothy hay.—J. N. Aitken.

ELLENBERGER, H. B., NEWLANDER, J. A. and JONES, C. H. **Effects of feeding different grades of hay and cod-liver oil concentrate to dairy cattle. 4. From birth through one to three lactations.** *Univ. Vermont Agric. Exp. Stat. Bull.* No. 580, June 1955, pp. 32.

Previous papers (see Absts. 326, Vol. 22; 1725, Vol. 24; 4319, Vol. 25) in this series have described the effect of feeding the rations outlined below on the performance of calves from birth to 360 days of age and of heifers from 361 to 720 days of age. The present paper describes the lactation performance of cows from the first generation of calves and of some of their second and third generation descendants. In all cases the lifetime nutritional status was known. First-generation calves were divided into 4 groups and given good or late-cut poor hay, each with or without cod liver oil supplement. Successive generations were fed in the same way as their parents. All animals received a daily grain ration with added salt throughout their lifetime. No Ca or P supplement was offered. It was concluded that the use of cod liver oil to provide extra vitamins A and D was unnecessary when good hay was given. Vitamin supplements may be necessary when late-cut poor hay is given to young animals. Homegrown hays and silages provide adequate amounts of Ca and P when given along with simple grain mixtures. The practice of adding such items as ground limestone and steamed bonemeal to dairy rations is considered unnecessary.—J. N. Aitken.

CARMAN, G. M. **Interrelations of milk production and breeding efficiency in dairy cows.** *J. Animal Sci.*, 1955, **14,** 753–759. [Div. Animal Husb., Iowa State Coll. Agric. Exp. Stat., Ames.]

Data on 1646 lactation intervals of 763 cows were used to estimate statistically the repeatability and heritability of time to first oestrus after calving, time from first service to conception and number of services per conception. It was found that the repeatability and heritability of all 3 measures of breeding efficiency were zero. The period from calving to first oestrus was correlated with level of production in the previous lactation. It is concluded that selection for breeding efficiency cannot be very effective.—J. N. Aitken.

1206

KOSHI, J. H. and PETERSEN, W. E. **Complementary milk and its relationship to lactation.** *J. Dairy Sci.*, 1955, **38,** 788–796. [Dept. Dairy Husb., Univ. Minnesota, St. Paul.]

Complementary milk is here understood to mean the amount of milk obtained after normal milking by hand, and after machine milking followed by hand stripping. The complementary milk was obtained after injection of 10 units oxytocin intravenously and further hand stripping. The cows were tested about once a week over a period of a year.

From 62 cows in over 1300 tests, from 0·1 to 13·3, average 1·7, lb. complementary milk was drawn at a milking: this was 1·2 to 70·9, average 11·3, per cent. of the total milk. The percentage of butterfat was from 6·1 to 22·5, average 13·2, and was positively related to the percentage butterfat of normal milk and the percentage of complementary milk. The amount, but not the percentage, of complementary milk decreased with advance of lactation and consequent decrease in yield of normal milk. The percentage of complementary milk was independent of the age of the animal and the amount of normal milk.

Persistency of lactation was not related to the age of the cow, the highest weekly quantity of milk produced or the trend of butterfat percentage, but the earlier in lactation the peak yield was reached, the poorer was persistency. There was a negative correlation between persistency and percentage of complementary milk.

The weekly injection of oxytocin did not appear to have any effect on total milk production.

1207

TURNER, H. G. **Sources of variation in residual milk and fat in dairy cows: their relation to secretion rates and persistency of lactation.** *Austral. J. Agric. Res.*, 1955, **6,** 514–529. [Div. Animal Health and Prod., C.S.I.R.O., Animal Health Res. Lab., Melbourne.]

The primary and residual milk yields of 12 cows were recorded in both early and late lactation and after milking intervals of 10, 14 and 24 hr. The residual milk was collected after intravenous injection of posterior pituitary extract. Butterfat was estimated in both primary and residual milk. Statistical analysis of the results showed that there was a high positive correlation between the amount of residual milk and total yield. With milking intervals of 10 and 14 hr. the mean residual milk yield was 17·8 per cent. of the total yield and with a 24-hr. interval it was 13·9 per cent. Cows showing low persistency in lactation gave high residual milk yields. There was little difference in milk secretion rate in cows milked at 10- or 14-hr. intervals. Secretion rates were reduced by

15 per cent. when a 24-hr. interval was imposed. Fat percentage increased with increasing length of milking interval.—J. N. Aitken.

1208

TURNER, H. G. **The effect of unequal intervals between milkings upon milk production and diurnal variation in milk secretion.** *Austral. J. Agric. Res.*, 1955, **6**, 530–538. [Div. Animal Health and Prod., C.S.I.R.O., Animal Health Res. Lab., Melbourne.]

Three pairs of identical and 2 pairs of fraternal twins were used. During an experimental period of 16 weeks one member of each set was milked at intervals of 11 and 13 hr. and the pairmates at intervals of 8 and 16 hr. Milk yield and butterfat percentage were recorded and also residual milk and fat. Total milk production was not significantly affected by milking at unequal intervals and fat percentage also was unaffected. There was no definite effect of milking interval on rate of milk secretion.—J. N. Aitken.

1209

ELLIOTT, G. M. and BRUMBY, P. J. **Rate of milk secretion with increasing interval between milking.** *Nature*, 1955, **176**, 350–351. [Ruakura Animal Res. Stat., Hamilton, N.Z.]

The rate of milk and fat secretion was measured in 4 trials in which the experimental design eliminated any possible effect of the length of the preceding milking interval. Residual milk was collected after injection of pitocin. The results showed that there was no diminution in the rate of secretion of milk or fat with increasing length of the milking interval up to 24 hr. It is concluded that milking twice daily at intervals of unequal length has no serious effect on rate of secretion.

J. N. Aitken.

AMSCHLER, J. W. and PAMMER, H. Ersatz des Eiweisses durch Harnstoff bei alpiner Spätweide. [**Replacing protein by urea on late Alpine pastures.**] *Bodenkultur*, 1954, **8**, 50–53. [Inst. Tierzucht, Hochsch. Bodenkultur, Vienna.]

This experiment at an elevation of 950 metres above sea level lasted from 13 August to 4 November 1952. Thirty-six Murboden cows feeding on alpine pasture (supplying in October 25 g. digestible protein in 125 g. starch equivalent) and hay, received from 10 September to 7 October a supplement of urea sprinkled over dried [beet] slices soaked in molasses, urea 150, dried slices 750 and molasses 400 g. per cow daily. Daily milk recording showed that with the urea supplement the decline in milk production due to seasonal deterioration of the high pasture was half that found in the same cows in 1951. During the first week some of the cows were unwilling to take the urea, but it had no ill effect on the health of the cows or on the quality of the milk or butter.—W. M. Deans.

1211

PARHAM, B. T., FRYE, J. B. (Jr.), KILPATRICK, B. L. and RUSOFF, L. L. **A comparison of ammoniated molasses, urea, and cottonseed meal as a source of nitrogen in the ration of dairy heifers.** *J. Dairy Sci.*, 1955, **38**, 664–668. [Louisiana Agric. Exp. Stat., Baton Rouge.]

The value of ammoniated molasses and urea when they replaced cottonseed meal in a normal concentrate ration was studied in a double reversal experiment with 3 comparable groups of dairy heifers. The experiment was continued through 3 periods of 28 days. The control ration was, per cent., oats 30, maize 44·5, cottonseed meal 11·0, cane molasses 12, steamed bonemeal 1·50 and salt 1·00. The 2 experimental rations were adjusted so that the ammoniated molasses and urea replaced 30 per cent. of the protein equivalent in the concentrate ration and supplied 18 per cent. of the protein equivalent in the total ration. There was no significant difference between the groups in rate of liveweight gain. The use of ammoniated molasses and urea did not affect the palatability of the feed. When urea was given more feed was required per unit of gain.—J. N. Aitken.

1212

DAVIS, R. F., WASSERMAN, R. H., LOOSLI, J. K. and GRIPPIN, C. H. **Studies on the availability of nitrogen from various ammoniated products for rumen bacteria and dairy cattle.** *J. Dairy Sci.*, 1955, **38**, 677–687. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Experiments *in vitro* with rumen bacteria and balance studies with 4 steers of dairy type were made. The ammoniated by-products were the residues from the manufacture of furfural, ammoniated molasses and dried distiller's molasses solubles. The results of both types of study showed that the N in such products was not as freely available to rumen bacteria or to the hest animals as the N in urea or other sources of N. More research is necessary to find a suitable source of N.P.N. for ruminants.—J. N. Aitken.

NEVENS, W. B., HARSHBARGER, K. E., ROLLINS, G. H., BURK, P. C., GARDNER, K. E. and KENDALL, K. A. **High-protein corn as a source of protein for dairy cows.** *Univ. Illinois Agric. Exp. Stat. Bull.* No. 586, March 1955, pp. 21.

The productivity of different strains of hybrid maize was compared in field plot trials. The

strains used were U.S. Hybrid 13, Illinois High Protein and 3 commercial strains. At harvest the loads were weighed and random samples were taken for analysis. The crops were ensiled and later used for feeding and digestion trials. All strains gave good yields of fresh material when grown on productive soil. Illinois High Protein yielded less dry matter per acre but almost as much protein as the other strains harvested at the same time. The protein content of the grain of Illinois High Protein on a dry matter basis was nearly 50 per cent. above that of the grain of other strains grown on the same field.

In digestibility trials with rabbits the digestibility of the protein of Illinois High Protein silage was above that of the other silages. All silages proved satisfactory for milk production in cows. It was concluded that the use of high-protein strains of maize would make it possible to reduce the amounts of protein concentrates normally given for milk production.—J. N. Aitken.

1214

VOLCANI, R. and SCHINDLER, H. **A comparison of cowpeas with maize as feed for dairy cows.** *Ktavim, Rec. Agric. Res. Stat. Rehovoth*, 1953, **4**, 5–8.

In 3 experiments maize and cowpeas were compared as green fodder for dairy cows. When all or half of the maize normally given, about 50 kg. daily, was replaced by cowpeas supplying about the same dry matter the normal decline of milk yield was reduced. The protein content of the cowpeas was higher than that of the maize, and was sufficient to satisfy most of the protein requirement of the cows, thus saving concentrates. The response to cowpeas was immediate and it was thought that protein alone could not be responsible for the improved milk yield.

1215

NEVENS, W. B. and KENDALL, K. A. **Sorghums and soybeans as silage crops for milk production.** *Univ. Illinois Agric. Exp. Stat. Bull.* No. 578, July 1954, pp. 62.

This investigation was planned to obtain information on the value of silages made from different species of sorghum, including sweet sorghum, kafir, milo, broomcorn and Sudan grass, or from soya beans. A further object was to estimate the protein content and protein yields of the forages and to compare the feeding value of sorghum silage with that of maize silage. A study was made also of the optimum stage for harvesting for silage and of the effect on yield when sorghums and soya beans were interplanted. The trials were made during a 5-year period from 1943 to 1947.

Estimates of yield were obtained by sampling the standing crops and by weighing the complete harvest from a block or field. In most of the trials the yields of dry matter exceeded the average yields for similar crops grown under Central Illinois conditions. The forages giving the highest yields were sweet sorghum, kafir, broomcorn and maize; the yield of dry matter from soya beans was comparatively low. The yields of protein in most cases were less than 600 lb. per acre.

Among conditions affecting the yields of forage were length of growing period, date of planting, date of harvest and variety. There was little advantage in interplanting soya beans with sorghums or maize.

Silages made from a mixture of sweet sorghum and kafir or Sudan grass and soya beans were found to be adequate for milk production, although milk yields were not as well maintained as with maize silage. Broomcorn silage was not very palatable and milk yields were below those with maize silage.

Complete data are presented.—J. N. Aitken.

1216

WAUGH, R. K., POSTON, H. S., MOCHRIE, R. D., MURLEY, W. R. and LUCAS, H. L. **Additions of hay to corn silage to maximize feed intake and milk production.** *J. Dairy Sci.*, 1955, **38**, 688–692. [N. Carolina Agric. Exp. Stat., Raleigh.]

Sixty cows were used in 6 trials to determine the amount of hay to be added to a ration of maize silage given to appetite to obtain maximum dry matter intake and milk production. During a 28-day standardising period each cow was offered maize silage to appetite and 1 lb. hay per 100 lb. liveweight, and 1 lb. grain per 4 lb. fat-corrected milk. In a 56-day experimental period the following 4 levels of hay were compared in 15 replicates: 1·00, 0·50 and 0·25 lb. per 100 lb. liveweight, with one group receiving none. Concentrates were reduced by 5 per cent. during this period. The actual levels of hay consumption were 0·83, 0·47 and 0·24 lb. per 100 lb. liveweight. Statistical analysis of the results showed that maximum dry matter intake was achieved by the groups which consumed 0·83 lb. per 100 lb. liveweight. Milk and fat production were highest in the group receiving 0·47 lb. hay.—J. N. Aitken.

1217

SEATH, D. M., BASTIN, G. M., LASSITER, C. A. and ELLIOTT, R. F. **Value of ground hay in the grain mixture of milk cows.** *Kentucky Agric. Exp. Stat. Bull.* No. 607, February 1954, pp. 12.

The effect on milk production of adding 23 to 37 per cent. ground alfalfa or soya bean hay to simple grain mixtures was studied in 2 double reversal trials each with 3 groups of 6 cows. When the grain ration contained from 23 to 27 per cent. ground hay, grain had to be increased by 8 per cent. and when it contained 37 per cent. hay an additional 13 per cent. of grain was required. Giving hay did not affect the palatability of the mixtures either way. Digestibility of the dry matter of the whole ration was reduced slightly by the addition of hay.—J. N. Aitken.

1218

HALLEY, R. J. **Certain pasture variations and their effect upon the dairy cow.** *J. Brit. Grassland Soc.*, 1955, **10,** 229–239. [Seale Hayne Agric. Coll., Newton Abbot, Devon.]

A pasture with herbage at 4 stages of maturity simultaneously was grazed by pairs of cows in a Latin square design. The stage of maturity was regulated by cutting the pasture from 3 to 9 weeks before grazing commenced. In 4 trials grazing periods were of 2 days, and between experimental periods the cows were allowed to graze herbage similar to the experimental herbage they were to be moved to for one day. A statistically significant increase was obtained by grazing the less mature pasture in only one of these experiments. Generally the chemical composition of the herbage on the several plots was similar, though there was a two- to four-fold difference in dry matter yield. In a fifth trial 2 herbages differing in maturity and chemical composition were grazed in a single-reversal design with 4-day periods. Cows grazing the less mature herbage yielded significantly more milk. In no trial was the butterfat or solids-not-fat content affected, nor could the technique used detect variations in herbage consumption. Observations showed that total grazing time decreased with increasing maturity of the herbage.

J. L. Corbett.

1219

SEATH, D. M., LASSITER, C. A., BASTIN, G. M. and ELLIOTT, R. F. **Effect of kind of pasture on the yield of TDN and on persistency of milk production of milk cows.** *Kentucky Agric. Exp. Stat. Bull.* No. 609, March 1954, pp. 11.

This trial was made during a 3-year period from 1951 to 1953. Four experimental pastures, each of 3·12 acres, were sown with the following mixtures: plot 1, 8 lb. orchard grass and 1½ lb. ladino clover; plot 2, 8 lb. Kentucky 31 fescue and 1½ lb. ladino clover; plot 3, 18 lb. Kentucky 31 fescue; plot 4, 16 lb. Kentucky bluegrass and 1½ lb. ladino clover. All plots were dressed with 200 lb. muriate of potash per acre at the time of sowing. In addition the fescue plot received 100 lb. nitrate of ammonia per acre in April and again in July in each year. During the last 2 winters all plots were dressed with barnyard manure. A variable number of Jersey and Holstein cows grazed the plots at intervals in each year. Milk production and bodyweight changes were recorded. From these data yields of total digestible nutrients were calculated.

The average persistency of milk production during the 3 grazing seasons was 98·3 for the orchard grass-ladino plot, 89·2 for the fescue-ladino, 87·2 for the bluegrass-ladino and 81·4 for the fescue alone. The estimated yields of total digestible nutrients per acre were 1726, 1789, 1760 and 2327 lb., respectively, for plots 1, 2, 4 and 3. It is concluded that the poor performance of the cows on the fescue plot was due to the effect of unpalatable herbage on appetite. The feeding value of the fescue could be improved by sowing it in a mixture with a ladino clover.—J. N. Aitken.

1220

GAALAAS, R. F. and ROGLER, G. A. **Grazing and grass-silage feeding studies at the Northern Great Plains Dairy Station.** *U.S. Dept. Agric. Tech. Bull.* No. 1115, June 1955, pp. 30.

Attempts were made to extend the length of the grazing season beyond that obtained from native pastures by the use of introduced grasses and legumes. During the 5-year period of study annual average rainfall was 12·55 in. and average monthly temperatures were below 32° F. during November-March inclusive, and reached a maximum of 64° to 69° F. during June-August. Combined results from the use of Sudan grass, crested wheat grass, and grass and lucerne pastures showed that length of the grazing season and milk production per acre were increased by 50 to 100 per cent. compared with native pastures, and the quality of the forage was improved. For the production of winter feed the yield from a mixture of oats and peas grown for silage was greater than from a mixture of wild rye and sweet clover and the crop was preferred to maize grown for silage both because of easier cultivation and because of the higher content of crude protein.—J. L. Corbett.

1221

LOOSLI, J. K., DAVIS, R. F. and WARNER, R. G. **Studies on the productive value of roughages and concentrates for lactation.** *J. Dairy Sci.*, 1955, **38,** 797–804. [Cornell Univ., Ithaca, N.Y.]

A series of trials was made with cows to determine the effect on milk production of replacing part of the roughage in an all-roughage ration with concentrates supplying equal amounts of total digestible nutrients (TDN) or estimated net energy. When the roughage was replaced by concentrates on an equal TDN basis but with slightly more

estimated net energy, milk production (fat-corrected) increased from 22·2 to 24·7 lb. per head daily. Replacement with concentrates on the estimated net energy system resulted in an increase of only 0·8 lb. milk daily. It is concluded that estimated net energy gives a better indication of the energy value of roughages than TDN. The suggestion by other workers that concentrates contain a specific unidentified substance which stimulates milk production is not supported (see Absts. 3036, Vol. 22; 1378, Vol. 25).—J. N. Aitken.

1222

RICHTER, K. and BECKER, M. Vergleichende Versuche über die ernährungsphysiologischen Wirkungen hoher Mengen an Rübenblattsilage und Maissilage im Futter von Milchkühen. [**Comparative experiments on the nutritional effects of large quantities of beet leaf silage and maize silage in the ration of milk cows.**] *Züchtungskunde*, 1955, **27**, 63–71. [Inst. Tierernähr., Forschungsanst. Landwirtsch., Brunswick, Völkenrode.]

The method was similar to that described in Abst. 3649, Vol. 23. The 2 cows were in their second lactation and still growing. For the first 3-week fore-period and 10-day experimental period their rations included 45 kg. beet leaf silage daily, and in the second fore-period and 10-day experiment, 32 kg. maize silage.

The beet leaf silage was more acceptable than the maize silage. Despite the higher water content of the beet silage the cows drank more with it, so that their total water intake was 95 to 100 litres daily in the first period and 68 to 70 in the second, and the mean urine volumes for the 2 cows were 32 and 29 litres in the first and 14 and 14 in the second. The beet silage contained 12·08 per cent. crude protein, the maize 6·77 per cent.

Both cows retained N in the first period, 6·47 and 22·54 g. daily, and lost N in the second, 4·56 and 9·26 g. The intakes of oxalic acid in the first period were 261 and 274 g. daily and those of Ca 216·4 and 225·1 g.; one cow lost 2·06 g. Ca daily and the other retained 4·10 g. In the second period the corresponding values were oxalic acid 32·5 and 32·5 g., Ca 91·9 and 92·1 g., and both cows retained Ca, 5·31 and 3·64 g. daily. P balances were positive in the first period, when Ca phosphate was given, and negative in the second, when there was no mineral supplement.

1223

LEROY, A. M. and ZELTER, S. Z. Recherches sur l'efficacité alimentaire des marcs de pomme fermiers. 4. Effet de l'ingestion de doses croissantes d'ensilage de marcs sur le niveau des sécrétions lactée et lipidique de la vache. [**The feeding value of cider apple residues. 4. Effect of ingestion of increasing amounts of apple silage on milk and fat secretion in the cow.**] *Ann. Zootech.*, 1955, **4**, 69–91. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

For previous parts see Abst. 5330, Vol. 24 and Abst. 1419, Vol. 25.

In 2 trials the effect on liveweight, milk yield and butterfat percentage of giving silage made from cider apple residue in place of part or all of the fodder beet in rations for dairy cows was investigated. The cows in each trial got the same concentrates. In the first trial there were 2 groups of 6 cows, and the trial was in 4 periods of 21 days. In the first period both groups got only beet, supplying 32 per cent. of the dry matter. In periods 2, 3 and 4, respectively, group 1 got 25 per cent. of the dry matter supplied by beet, and no silage; no beet and 31 per cent. silage; and no beet and 22 per cent. silage. During these periods group 2 got no beet and 32 per cent. silage; 23 per cent. beet and no silage; and 16 per cent. beet and no silage. In the second trial one group of 10 cows was given, in successive periods, 31 per cent. beet, 14 per cent. beet and 22 per cent. silage, and 18 per cent. beet and 15 per cent. silage.

The replacement of part or all of the fodder beet with silage of cider apple residue did not affect milk yield or percentage butterfat, or liveweight of the experimental cows. The silage was readily accepted up to 30 kg. per head daily. No ill effect was caused by the alcohol, about 2·1 per cent. of the fresh material.—T. D. Bell.

1224

VOLCANI, R. and RODERIG, C. **A preliminary report on the feeding of cattle and sheep with nitrogen-enriched orange peels.** *Ktavim, Rec. Agric. Res. Stat. Rehovoth*, 1953, **4**, 21–22.

Dairy cows readily ate up to 10 kg. daily of orange peel silage enriched with N by soaking in ammonia solution. The enriched silage was palatable as long as the added N did not exceed 3 per cent. of the dry matter. The processed silage had an N content of from 3·5 to 3·8 per cent. of dry matter.

For about a week sheep were reluctant to eat the dried enriched orange peel, with a total N content of 2·5 to 3 per cent., but when they became used to it they took 1 kg. daily. No ill effect occurred in either cows or sheep.—T. D. Bell.

1225

ROCHA, J. O. and RIVAROLA, V. R. Los cactus como alimento para el ganado. [**The cactus as feed for cattle.**] *Rev. Agric., Costa Rica*, 1955, **27**, 229–231.

The prickly pear (*Opuntia ficus indica*) is described. It is rich in vitamins A and C, and has some of the B complex vitamins. The juice is used medicinally, and from the fruit wine and vinegar are produced. It has 92 per cent. moisture, but for stock the fleshy leaves and fruit could be a useful source of carbohydrate; they contain only negligible quantities of protein. Particularly in dry areas it would be of great value.

T. D. Bell.

1226

MUELLER, W. S. and BLAZYS, K. **Effect of feeding antioxidant (cacao shell) on the stability of the milk fat.** *J. Dairy Sci.*, 1955, **38**, 695–696. [Univ. Massachusetts, Amherst.]

A Jersey cow whose milk was susceptible to oxidative deterioration was used in a feeding trial extending over 4 periods: pre-experimental, 1 week experimental feeding of cacao shell at the rate of 2·3 lb. daily, a 2-week post-experimental period and a 4-week post-experimental period. The basal ration was of chopped green maize, alfalfa hay and a grain mixture. The anti-oxidant effect of cacao shell was measured by the thiobarbituric acid test and taste tests on the milk, and by the same tests plus peroxide value and colour on the butter oil. The milk was sampled and to a portion of each sample 4 p.p.m. $CuSO_4$ was added to hasten oxidative deterioration.

The feeding of cacao shell increased the resistance of the milk to oxidative deterioration. This effect was most pronounced at the end of the 2-week post-experimental period. The maximum effect on butter oil was also obtained during this period.—J. N. Aitken.

1227

LARSEN, L. H. Beretning om et akklimatiseringsforsøg med dansk kvaeg i Italien 1954 og et tillaeg om ydelser af dansk kvaeg. [**Report of an experiment in acclimatisation of Danish cattle in Italy, 1954, and an appendix on the yields of Danish cattle.**] *Forsøgslab. København Beretn.*, 1955, No. 281, pp. 64. In Danish and Italian.

This report gives a condensed account of the size and production of the Red Danish (Røde Danske) and Black and White Danish (Sortbroget Dansk) breeds of cattle. The Black and White resembles, and is related to, the Friesian and has been accepted in Mediterranean countries for a long time. After some difficulty permission was got from the Italian government to set up a demonstration herd of cows of both breeds at Sutrium, a farm 45 km. north of Rome. In spite of a gruelling journey by rail during which 2 of the cows died and some calved prematurely, and in spite of conditions which, by Danish standards, were unsatisfactory, both breeds did extremely well. The cows were stall-fed for the whole lactation of 304 days in ill ventilated buildings, so that the temperature and humidity were more unfavourable than they need have been. There was no pasture for the Danish herd; the roughage was of variable quality because of poor harvesting practices and poor storage and there was not enough of it. Fodder crops were so small relative to the total stock carried that both roughage and concentrates were brought. Measures required to put the Italian farm on a sounder basis are suggested.

In spite of all these drawbacks, the Red cows in 304 days produced on the average 4640 kg. of 4 per cent. milk for 3248 feed units, which is a more economical performance than that of recorded cows in Denmark, 4226 kg. of 4 per cent. milk for 3495 feed units.—I. Leitch.

1228

SCHINDLER, H. **Seasonal variations in productivity of dairy cows under Israel conditions.** *Ktavim, Rec. Agric. Res. Stat. Rehovoth*, 1953, **4**, 41–46.

Records of 109 lactations from the Israel Herd Testing Association were studied with reference to the influence of season and month of calving on milk and butterfat yields and butterfat percentage. For each month of calving considered separately, yields of milk and butterfat showed a seasonal trend, being highest from February to April; milk yield was lowest in October and November, and butterfat yield from June to November. Butterfat percentage was lowest in June and July and highest from November to January. Highest yields of milk and butterfat were obtained from cows calving in autumn, and lowest from those calving in January and from March to July.

Since the cows are fed in the same way throughout the year, the possibility of the effect of season on the sex and thyroid glands is discussed.

SMOLIAK, S. and PETERS, H. F. **Climatic effects on foraging performance of beef cows on winter range.** *Canad. J. Agric. Sci.*, 1955, **35**, 213–216. [Range Exp. Stat., Manyberries, Alta.]

Hereford, Shorthorn, Angus, quarter-bison Cattalo and half-bison Cattalo breeding cows were wintered on short grass prairie. A record of the number of cattle grazing the upland range at midday was made throughout January to April when the mean monthly temperature did not exceed 17·6° F. There was a significant positive partial correlation between foraging frequency and temperature, but not between foraging frequency and daily wind velocity or the amount of supplemental feeding. More foraging was done by Cattalo than by domestic cattle.—J. L. Corbett.

REPRODUCTION

1230

MÄKELÄ, A. and OITTILA, R. Tiineysajan pituus Viikin opetus- ja koetilan Ayrshirekarjassa. **[Length of gestation in Ayrshire cows on the Viik experimental farm.]** *Maataloust. Aikakausk.*, 1955, **27**, 77–84. [Dept. Animal Husb., Univ. Helsinki.] English summary.

Records of 382 calvings of Ayrshire cows were studied. The length of gestation of cows carrying single calves was from 265 to 293, average 279·9 days. Twins were carried for 6·78 days less than single calves, and bull calves were carried 0·82 of a day longer than heifers. The gestation period for first calves was not significantly different from subsequent periods. When third and later calvings were considered, weight and degree of fatness of dam did not influence the length of the gestation period. Between duration of gestation and birthweight of the calf a positive correlation of $r = 0{\cdot}146$ was found when all data were considered. Within cows the correlation was $r = 0{\cdot}333$. Cows calving for the first time had calves 2·98 kg. lighter than those calving for the fourth time. The weight of the calf and the weight of the dam showed a positive correlation of $r = 0{\cdot}133$. Bull calves were 2·22 kg. heavier than heifer calves. (From summary.)

BAKER, F. N., VANDEMARK, N. L. and SALISBURY, G. W. **Growth of Holstein bulls and its relation to sperm production.** *J. Animal Sci.*, 1955, **14**, 746–752. [Dept. Dairy Sci., Univ. Illinois, Urbana.]

Bodyweights, heights at withers and heart girths of 9 bulls were recorded from 4 to 160 weeks of age. Semen was collected regularly from 39 years of age.

Statistical analysis of the data showed that weight and age were highly correlated, as were also the logarithm of the weight and heart girth. For heart girths up to 47 in. the regression of the logarithm of the weight in lb. (Y) on heart girth in inches (X) was $Y = 0{\cdot}7572 + 0{\cdot}03783\ X$. The regression for heart girths over 47 in. was $Y = 1{\cdot}7983 + 0{\cdot}01686\ X$. Sperm numbers per ejaculation were significantly correlated with age and weight.—J. N. Aitken.

HUNDT, K. W. Bestehen Relationen zwischen der Dauer der Tragezeit, dem Geburtsgewicht der Karakullämmer und dem Gewicht der Rohfelle? **[Are the length of gestation, the birthweight of Karakul lambs and the weight of the raw pelts related?]** *Züchtungskunde*, 1955, **27**, 9–16. [Wolfenbüttel.]

The study was made on lambs killed in 2 successive seasons at the *Tierzuchtinstitut*, Halle; 208 ram and 21 ewe lambs were pure Karakul and 47 ram and 21 ewe lambs were crossbred. The ranges and mean birthweights for these 4 groups, taken after the lambs were licked dry by the ewes, were, in kg., 2·7 to 6·3, 4·53; 3·2 to 5·6, 4·36; 2·4 to 6·8, 4·5; and 2·5 to 5·7, 4·1. The length of gestation ranged from 143 to 157 days, mean 150·5. The lambs were killed within 24 hr. after birth and the air-dried skins weighed from 122 to 262 g., mean 219·4 g.

Birthweight increased with duration of pregnancy. Skin weight increased with birthweight, but there was little relation between duration of pregnancy and skin weight. No relation was found between the proportion of outcross and the skin weight in the crossbred lambs, nor was any effect of the breed used for crossing detected.

1233

MUNRO, J. **Studies on the milk yields of Scottish Blackface ewes.** *J. Agric. Sci.*, 1955, **46**, 131–136. [Dept. Agric., Univ. Aberdeen.]

In trials with 42 Blackface ewes with single lambs over a 6-week period, the estimated average milk yield per ewe on a hill providing a high plane of nutrition was 159 lb. (range 86 to 220 lb.) and on a hill providing a low and variable plane of nutrition 96 lb. (range 65 to 131 lb.). Average daily liveweight gains of lambs were 0·72 and 0·43 lb., respectively. A linear regression was found between milk yield and daily gain. A highly significant correlation existed between milk yield and liveweight of ewe. It was estimated that 5·5 oz. milk were required to give 1 oz. liveweight increase. Milk yields and liveweight gains of lambs are compared with published results from other breeds. Data on milk consumption are included.—J. C. Gill.

1234

VOLCANI, R. and EYAL, E. **Raising lambs on a restricted milk diet.** *Ktavim, Rec. Agric. Res. Stat. Rehovoth*, 1953, **4**, 35–40.

In Israel fat-tailed Awassi sheep are kept for milk. Experiments were made to investigate the possibilities of rearing the lambs on limited amounts

of milk. In each of two experiments one group was allowed to suckle and another was fed by hand, from pails in the first experiment and from bottles in the second. By weighing the lambs before and after suckling it was estimated that the daily milk intake was 1·058 kg. in the first and 1·305 kg. in the second experiment. In controls selected at random from the flock the average daily intake was 1·126 kg. In both experiments both groups had access to concentrates after the first week. Hand feeding was started after the lambs had been with their dams for 3 days. It was difficult to persuade the lambs to feed from pails in the first experiment, and their growth rate was poor for the first week, but after that they surpassed the suckled lambs. They took 50·3 kg. milk per head in 69 days, compared with the estimate of 81·6 kg. in 77 days in the suckling group. In the second experiment bottle feeding was found to be easy. By this method the lambs were given 39·4 kg. milk in 49 days, while the corresponding group suckling got 80·6 kg. in 62 days. In this experiment growth was better in the suckling group, but both groups did well, better than either group in the first experiment.

SLEN, S. B. and WHITING, F. **Wool and lamb production as affected by the source of protein in the ration of the mature ewe.** *J. Animal Sci.*, 1955, **14,** 844–859. [Div. Animal Husb., Exp. Farms Serv., Canada Dept. Agric., Ottawa.]

Eight sources of protein were compared in 2 experiments each with 96 mature ewes on rations containing 7 per cent. total protein until 6 weeks before lambing and 11 per cent. thereafter. Lambs from ewes given lactalbumin were heavier at birth and at 6 weeks of age than those from ewes getting linseed meal, peas, alfalfa meal or urea. Fleece weights of ewes on lactalbumin were higher than those of ewes getting peas, urea or urea plus sulphur, but not higher than those of ewes on linseed or alfalfa meal. There was no difference between the values of linseed, alfalfa or soya bean meals for lamb or wool production and all were superior to meatmeal for wool production but not for lamb production. The proteins were superior to urea for lamb and wool production. No benefit resulted from the addition of organic sulphur to the urea. The composition of blood and milk was unaffected by the different rations.—J. C. Gill.

1236

BLACKWELL, R. L. and HENDERSON, C. R. **Variation in fleece weight, weaning weight and birth weight of sheep under farm conditions.** *J. Animal Sci.*, 1955, **14,** 831–843. [Dept. Animal Husb., New Mexico Coll. Agric. Mech. Arts, State College.]

Data on 1965 records of fleece weight from 660 ewes, 1295 records of weaning weight of lambs from 463 ewes and 2158 records of birthweight of lambs from 560 ewes were examined for 4 breeds of sheep. Variation of fleece weight was associated mainly with age of ewe and year of recording. In the Corriedale, Hampshire and Shropshire, weaning weights were associated with year, age of dam, age of lamb, sex and type of birth and rearing. In all breeds birthweights were significantly correlated with year of birth, age of dam, sex and type of birth. In the Dorset, season of birth influenced birthweight, but age of dam and weaning weight were not associated. Estimates for repeatability and heritability of these characters are included.

1237

HAYMAN, R. H., TURNER, H. N. and TURTON, E. **Observations on survival and growth to weaning of lambs from ewes with defective udders.** *Austral. J. Agric. Res.*, 1955, **6,** 446–455. [Div. Animal Health and Prod., C.S.I.R.O., F. D. McMaster Field Stat., Liverpool, N.S.W.]

Udder defects, including mechanical injury, mastitis and blind teats with no obvious sign of injury, were found in 6·3 per cent. of a flock of 342 Merino and 213 Merino × Border Leicester ewes aged from 1 to 7 years. The incidence increased significantly from 1·3 per cent. at 1 year old to 16·7 per cent. at 7 years old. There was no significant difference between breeds.

During 4 years 646 single lambs from Merino ewes were examined, and the effect of udder defects in the dams on birthweight, rate of gain from birth to weaning, mortality from birth to weaning and weaning weight of the lambs was studied. After adjustments for the effects of size and age of dam, length of gestation, coefficient of inbreeding and sire were made, it was found that lambs reared by ewes with defective udders had a lower rate of gain, weaning weight and survival rate. The effects were more serious in ewes with both sides defective than when only one side was defective. Birthweight was not affected.

1238

WILKINSON, W. S., O'MARY, C. C., WILSON, G. D., BRAY, R. W., POPE, A. L. and CASIDA, L. E. **The effect of diethylstilbestrol upon growth, fattening, and certain carcass characteristics of full-fed and limited-fed western lambs.** *J. Animal Sci.*, 1955, **14,** 866–877. [Dept. Animal Husb., Univ. Wisconsin, Madison.]

Lambs implanted with diethylstilboestrol and fed on a lower level than controls, so that all reached the same carcase weight at the same age, had greater values than controls for rate of gain, pelt weight, carcase length and percentage of water

in fat, but smaller values for dressing percentage, carcase finish and grade, and external fat thickness. There was no significant difference between treated and untreated lambs in wool weight, shrinkage, skin thickness, shank length, percentage of water in the muscle, eye muscle area, liver weight or percentage of ash in the shank bone. The effect of the stilboestrol in retarding the deposition of external fat was increased by limited feeding. When the feeding period was extended from 49 to 84 days lambs finished without significant difference from controls in respect of live grade score, thickness of external fat and percentage of water in external fat. Two hundred wether lambs were used in all.—J. C. Gill.

OLOFSSON, N. E. Utfodringsförsök med far vid Herrökna 1950–1951. [**Feeding experiments with sheep at Herrökna, 1950-1951.**] *Kungl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 106, 1954, pp. 8.

The effect was recorded of 4 different levels of winter feeding, 1·0, 1·2, 1·4 and 1·8 Scandinavian feed units (F.U.) per 100 kg. liveweight daily, on 32 Landrace ewes during and after pregnancy and on their lambs. The third group, receiving 1·4 F.U., had most lambs born, the smallest death rate for lambs and ewes, the highest lamb weight per ewe and only a slight decrease in the weight of the ewes during winter. These amply compensated for the extra cost. Only the last group had the same weight after pregnancy and both it and the first group had smaller weights of lamb per ewe than the other groups. With 32 non-pregnant Cheviot ewes about 2 F.U. per 100 kg. weight were found necessary to increase weight during winter. Three deaths occurred when the feed supplied only about half this.—A. Hepburn.

DALY, R. A. and CARTER, H. B. **The fleece growth of young Lincoln, Corriedale, Polwarth, and fine Merino maiden ewes under housed conditions and unrestricted and progressively restricted feeding on a standard diet.** *Austral. J. Agric. Res.*, 1955, **6**, 476–513. [Div. Animal Health and Prod., C.S.I.R.O., Wool Biol. Lab., Sydney, N.S.W.]

Four sheep of each breed in single pens were used in 2 consecutive trials. In the first they were given a high-quality diet to appetite for 12 months and in the second the same diet reduced in amount every 4 weeks and finally maintained at 20 per cent. of the original amount for 12 weeks. The absolute or relative value of the characters measured increased or decreased from Merino through Polwarth and Corriedale to Lincoln. For example, feed and water intake, liveweight and chest dimensions, fibre thickness, length and volume, clean wool, suint and total skin products, and clean wool and suint output per unit feed intake increased; total and primary follicle density, ratio of secondaries to primaries, wax output, and wax output per unit feed intake decreased. Body length and height, feed intake per unit net liveweight and total skin products per unit feed intake were similar for all breeds. Weight of wool, fibre thickness, growth in length and volume, and production of wax and suint were positively correlated with food intake. Wool growth was not influenced by a rise in atmospheric temperature, except for fibre thickness in the Lincoln. Wax production in all breeds was negatively correlated with rise in temperature. Rate of wool growth was positively correlated with fleece weight through fibre length but not through fibre thickness. A negative correlation was found between production of wool, wax and suint per unit feed intake and feed intake; wax per unit feed intake was negatively correlated with temperature and suint per unit feed intake was positively correlated with fleece weight.—J. C. Gill.

ZAKIROV, M. D. Vliyanie gornykh pastbishch na produktivnost' i zhivoi ves karakul'skikh ovets. [**The effect of mountain pastures on the productivity and liveweight of Karakul sheep.**] *Karakul. i Zver.*, 1955, **8**, No. 1, 9–17. [Inst. Animal Management Acad. Sci., Tadzhik SSR.]

Owing to the increase in arable land under cotton and other cash crops in Tadzhikstan it is necessary to use mountain pastures, since with the decrease of pasture in the plains and the increased number of livestock the plains pastures have become overstocked.

Experimentally one flock of sheep was taken to the mountain for the summer months while another flock was left on the plains. In the autumn the mountain sheep weighed 21·1 per cent. more than the flock that had been kept in the plains. They were also more productive, *i.e.*, had a higher percentage of twins, and the yearling lambs from the mountain ewes had a liveweight increase double that of their contemporaries from the plains.

The explanation of these differences was that after a period of growth of grass from the beginning of March to the middle of April, the plains pastures got burnt up with the heat. The mountain pastures, after the snow melted in May, continued to provide feed for a considerable time. Lambs born in the plains, after becoming accustomed to green fodder, had to fall back on their mother's milk when the pastures dried. On the mountain pasture both the ewes and their lambs were able to continue grazing for a considerable part of the

summer. By removing all the sheep to the mountains for the summer it was possible to maintain the grasslands in the plains in better condition, so that they could be used to better effect during the autumn, winter and early spring.

1242

MOROZOV, N. L. and GAEVSKAYA, L. S. Pastbishchnoe soderzhanie karakul'skikh ovets v predokotnyi period. [**Pasture management of Karakul sheep in the pre-lambing period.**] *Karakul. i Zver.*, 1955, **8,** No. 1, 7–9. [All-Union Sci. Res. Inst. Karakul Management.]

At the end of the winter the pastures are dry. Winter pastures supply from 32 to 45 feed units (F.U.) and 1·3 kg. digestible protein per 100 kg. fodder, which means a daily intake of 0·81 to 0·93 F.U., where an in-lamb ewe weighing 45 kg. needs 1·1 F.U. and 92 g. protein daily. In order to avoid this deterioration winter pastures should be grazed in rotation so that the last 2 months of the pre-lambing period are spent on fresh pasture. Winter pasture is deficient also in minerals; the Ca : P ratio is 8 : 1, instead of 2 : 1. Apart from rotation of winter pastures, the ewes should receive a supplement of concentrates, 300 to 400 g. per head daily, according to liveweight. The weaker ewes should also be given bonemeal at the rate of 8 g. P per 100 kg. liveweight. Without rotation of pastures and supplementary feeding the ewes lose between 10 and 31 per cent. of their weight, depending on the severity of the winter, and also show signs of vitamin deficiency.

1243

YURCHENKO, V. T. Opyt organizatsii tebenevki ovets. [**Practical experience of the organisation of free range pasturing of sheep.**] *Karakul. i Zver.*, 1954, **7,** No. 6, 16–18. [Karakul Sovkhoz "Volzhskii".]

As a result of correct use of pastures the sovkhoz "Volzhskii" saved 3400 tons of hay and 400 tons of concentrates during the year and only 1·3 per cent. of the sheep were lost. As the ground was covered with snow from the middle of November to 20 March these results were obtained only by letting the sheep out to the snowbound pastures; the plants under the snow were not frozen and kept their natural nutritive qualities even at very low temperatures. The sheep, however, were not able to maintain themselves exclusively on the pastures. Hay was given in the morning, and a second and larger feed of hay on their return in the evening. The amount depended on the weather and on the day's pasturing. The morning feed of hay was given on the pastures to accustom the sheep to follow the sledges out into the fields even at low temperatures such as — 30° C. During sharp frosts, when each sheep is given up to 1 kg. hay, they should be watered every 2 to 3 days; with increased rations of hay and when small amounts of concentrates are introduced into the ration, the sheep should be watered every day or every other day. With temperatures of — 10° C. and below and additional small amounts of hay up to 800 g., each sheep needs 2 to 2·5 litres of water every other day. Shortage of water was found to lead to abortion.—H. Scherbatoff.

PIGS

1245

SCHÄFER, H. and GRANZ, E. Boebachtungen über die Gewichtsverluste der Sauen während der Säugezeit. [**Loss of weight by sows during lactation.**] *Züchtungskunde*, 1955, **27,** 37–46.

A statistical study was made of weight changes in sows between the day after farrowing and the end of the fourth and eighth weeks of lactation. There were 57 Improved Landschwein sows which produced 240 litters and 2896 young, and 32 Berkshire sows which had 90 litters and 794 young. The Landschwein sows had at 8 weeks a mean of 9·1 pigs per litter and lost 16·3 ± 10·10 per cent. of their initial bodyweight, the Berkshires had 7·4 pigs and lost 14·1 ± 9·84 per cent. More weight was lost in the first month than in the second, when the young pigs had begun to eat solid feed. The sows received 2 kg. concentrates plus ¼ kg. for each piglet daily, with chopped green feed to appetite in summer and roots, but never potatoes, in winter. The Landschwein sows with the largest litters did not lose more weight than those with small litters, so the ration was probably sufficient for their requirements. There was a positive correlation between the total weight of the litter and the weight loss of the sow at 4 weeks, but not at 8 weeks. Very heavy sows had high litter weights and big weight losses at 4 weeks, very light sows

had light litters and smaller losses, but middle-sized sows showed less correlation between litter weight and bodyweight loss. Old sows with 9 or more litters, despite their large size, did not have heavy litters at 4 weeks and themselves lost less weight than young sows. The variation in weight loss at 4 and 8 weeks was less between 25 full sisters than between all the sows, showing a genetic influence.

Sows with a medium weight loss in their first lactation lived on the average longest and had the largest and heaviest litters ; those which lost little or no weight in the first lactation were poor performers later.—D. Duncan.

1246

COEY, W. E. **The relationship between the weaning weight of pigs and the number of pigs in the litter.** *Res. and Exp. Rec. Minist. Agric. N. Ireland*, 1952–53 (1955), **3,** 106–115.

Since selection of pigs for breeding is often done on the basis of prolificacy records, and litter weight at 8 weeks has been suggested as the most important measure of the efficiency of a breeding sow, it is desirable to know how the number of pigs in a litter will influence the weaning weight per pig. Earlier evidence on this point has been conflicting.

Analyses were made on the records of the Hillsborough herd of Large White pigs for the period 1933–1950, including results for all sows which produced 4 or more litters but excluding any litters not managed on the ordinary farm routine. . For each order of litter, the average weight per pig at 8 weeks decreased with increasing litter size, the effect being more marked for the first 2 litters than for the later ones. There was no evidence that there was a critical size of litter below which this effect did not operate. Consideration of the weights at 3 weeks and at 8 weeks showed that the greater part of the litter size effect was operative before the age of 3 weeks, the relation of 8-week weight per pig to 3-week weight per pig varying only slightly with litter size.

Over the period of these records, the level of supplementary feeding used in the Hillsborough herd was very low, and average weaning weights were often under 30 lb. Other published data, from herds with good supplementary feeding, have shown no litter size effect, and it is suggested that the different levels of supplementary feeding, rather than the different breeds of pigs involved, have been the cause of the contradictory results.

It is concluded that with successful supplementary feeding techniques there is no reason why large litter size should lead to low weaning weight, and that such techniques are even more important for first and second litters than for later litters.

1247

TEAGUE, H. S. **The influence of alfalfa on ovulation rate and other reproductive phenomena in gilts.** *J. Animal Sci.*, 1955, **14,** 621–627. [Ohio Agric. Exp. Stat., Wooster.]

In each of 4 trials 2 groups of gilts were used, one getting a ration containing alfalfa, and the other a similar ration with no alfalfa, but mineral and vitamin supplements to compensate. The experimental rations were given to the gilts, which were kept in dry lot, at least 19 days before they were served. They were served only once, and those that did not conceive, and some of those that did, were slaughtered, the latter early in gestation, for post-mortem examination. Birth-weights, litter numbers, vigour of newborn pigs and numbers surviving to 8 weeks of age were recorded.

The presence of alfalfa in the ration did not affect the breeding performance of the gilts that farrowed, as regards liveweight or vigour of the piglets, but the number of pigs born alive was significantly greater, as was the number which survived to weaning.

Of the animals killed and examined in early gestation those which had received alfalfa had a larger number of corpora lutea. The results suggest the presence in alfalfa of a substance which favourably influences ovulation rate and survival to weaning.—T. D. Bell.

1248

LENKEIT, W. and GÜTTE, J. O. Langfristige Untersuchungen zum äusseren und inneren Stoffwechsel des graviden und laktierenden Schweines. 1. Allgemeine Angaben zur Versuchsmethodik. [**Prolonged studies of external and internal metabolism of pregnant and lactating sows. 1. General account of methods.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 94–102. [Inst. Tierphysiol., Univ. Göttingen.]

Pigs kept in ordinary stalls and driven out every 2 to 3 hr. during the day and every 3 to 5 hr. at night were trained in a few days to urinate and defecate in a place where the excreta could be collected quantitatively. Metabolism studies could thus be made under more normal conditions than are possible with metabolism cages or harness. Some loss of urine in the stalls occurred when sows were in oestrus and in the last few days of pregnancy, but still the method was considered more accurate than the use of cages.

In studies of milk yield the piglets were allowed to suck at least 15, and up to 28, times daily. The number of young in the litter in such experiments should not be less than normal, since small numbers elicit only a small milk yield. When young pigs are to be weighed before and after suckling it is advisable to keep them in a light cage standing

permanently on the balance, since if they are picked up and weighed just before suckling they become so excited that accuracy is impaired. Correction was made for loss of weight by salivation by allowing piglets to suck the empty teats shortly after a feed. The losses found in this way ranged from a mean of 2 g. per feed in the first 5 days of life to 4·8 and 5·8 g. for pigs of 2 litters a month old.

For analysis of milk the litter was moved about in the first few days to ensure that at least 2 more teats were used than there were piglets. Then after a teat had been sucked for 8 to 10 sec. the piglet could be given another and the first one could be milked by hand. Different teats were used in succession.

The sows were fed twice daily and were given 2 to 3 litres of drinking water per kg. dry matter of the ration plus 0·8 litre per kg. milk yield. Foreperiods of at least 7 days were allowed on any ration before collections were made. For faecal collections 10-day periods were preferred, for milk and urine 5 or 10 days.—D. Duncan.

1249

HEIDA, J. De opfok van moederloze biggen. [**The rearing of motherless piglets.**] *Tijdschr. Diergeneesk.*, 1955, **80,** 616–623. [Beetsterzwaag.] English, French and German summaries.

The pigs were fed, 6 times a day at first, with synthetic milk on Nelson's formula (*Iowa Farm Science*, 1952, **10,** 147) in amounts increasing from 500 to 1750 g. daily. At 3 weeks they were given baby-pig meal mixed with water or buttermilk.

Of 1036 pigs fed in this way that did not have enough colostrum, 29·4 per cent. died; of 1457 that had enough colostrum, only 9·7 per cent. died. I. Leitch.

1250

GROOT, E. H. and MUYTJENS, E. E. Een vergelijkende proef met antibioticumhoudende en antibioticumvrije kunstmatige zeugenmelk voor de opfok van zeer jonge biggen. [**Comparative test of artificial milk with and without antibiotics in the rearing of very young pigs.**] *Landbouwk. Tijdschr.*, 1955, **67,** 497–504. [Lab. N.V. Chem. Fab. Noord-Holland, Beverwijk.]

Literature is briefly reviewed. In a test with 4 and 5 pigs of one litter, taken from the sow after 4 days and given an artificial milk, 2 in the first group without antibiotic died; the other 2 had diarrhoea and poor appetite. Appetite was good in the group which got 100 mg. terramycin per kg. air-dry "milk", and growth and condition were satisfactory.—I. Leitch.

CUNNINGHAM, H. M. and BRISSON, G. J. **The utilization of lard by baby pigs.** *Canad. J. Agric. Sci.*, 1955, **35,** 371–376. [Chem. Div., Sci. Serv., Canada Dept. Agric., Ottawa.]

In 2 digestibility trials 12 baby pigs were fed on liquid purified diets with 13 per cent. solids. The diets contained 1·5, 3·0 and 4·5 per cent. fat, as lard. During each test period the diets were given to appetite for 5 days, and then held constant. The apparent digestibility of fat, protein, carbohydrate and dry matter was estimated at 1 to 2, 3 to 4, 6 to 7 and 8 to 9 weeks of age. The apparent digestibility of the lard was not affected by the percentage of lard in the diet, but increased significantly from 83·8 to 90·3 per cent. in the first trial and from 91·3 to 97·6 per cent. in the second trial from the second to the fourth week of age, and then remained constant. The apparent digestibility of protein and carbohydrate was similarly affected by age but not by the composition of the diet. The apparent digestibility of the dry matter increased with age, but decreased with increasing percentage of fat in the diet, because at the higher levels more fat was excreted in the faeces. Data on metabolic fat excretion were obtained from 4 pigs fed on a fat-free diet from 2 to 56 days of age, and from these data the true digestibility of the lard was calculated to be 1·23, 0·70 and 0·59 per cent. higher than its apparent digestibility in the low-, medium- and high-fat diets, respectively.—T. D. Bell.

1252

BECKER, D. E., NESHEIM, M. C., TERRILL, S. W. and JENSEN, A. H. **Problems in the formulation of a semi-synthetic diet for amino acid studies with the pig.** *J. Animal Sci.*, 1955, **14,** 642–651. [Illinois Agric. Exp. Stat., Urbana.]

A synthetic diet designed to be low in L-lysine and L-tryptophan was made up of dried skimmed milk, zein, maize starch, dextrose, wood flock, maize oil, minerals, vitamins and amino-acids. This was used in feeding and N balance trials with pigs of about 20 lb. liveweight.

The synthetic diet with 18 per cent. skimmed milk and 5 per cent. zein, with the tryptophan deficiency rectified and only 0·54 per cent. L-lysine, produced satisfactory rate and efficiency of gain, which were not improved by adding more L- or DL-lysine. When the percentage of milk was reduced to 12 per cent., zein increased to 7·5 per cent., and the L-lysine content was only 0·37 per cent., growth was poor, and added L- or DL-lysine did not improve it. A similar diet, not corrected for tryptophan deficiency, with 1 per cent. added L-lysine, was used and again growth and efficiency were poor. Supplements of 0·04 to 0·16 per cent.

L-tryptophan all improved rate and efficiency of gain, though they were still not satisfactory. The best level was 0·02 per cent., which was significantly better than 0·04 and 0·16 per cent. DL-Tryptophan, 0·08 per cent., depressed growth and efficiency.

A diet with no skimmed milk was used to estimate the apparent digestibility of zein, 11 per cent., as a source of protein, without amino-acid supplements. The apparent digestibility was 44·8 per cent. The pigs did not gain weight, but were in positive N balance.

In all the amino-acid trials some pigs showed signs of locomotor incoordination and coma. The syndrome was produced experimentally with a diet containing skimmed milk and zein but with 50 per cent. dextrose. Bloat was seen consistently in the evenings and was the cause of some deaths. Sometimes vomiting relieved the stress and pigs recovered. Post-mortem examination revealed no pathogenic organism, but yeast organisms were present and active in the stomach and caecum.

T. D. Bell.

1253

BECKER, D. E., NOTZOLD, R. A., JENSEN, A. H., TERRILL, S. W. and NORTON, H. W. **The tryptophan requirement of the young pig.** *J. Animal Sci.*, 1955, **14,** 664–673. [Illinois Agric. Exp. Stat., Chicago.]

In 3 experiments pigs weighing 30 lb. were used to estimate tryptophan requirement, and the effect of antibiotics and different levels of protein in the diet on this requirement.

The protein levels compared were 15 per cent., supplied largely by yellow maize and fishmeal, and 20 per cent., made up by the addition of 5 per cent. of zein. Such diets did not supply sufficient tryptophan for growth. Supplements of L-tryptophan were added. At the lower protein level it was found that 0·115 per cent. total L-tryptophan in the ration gave the best growth and efficiency, and this was considered the minimum requirement. The protein level did not affect the requirement. There was evidence that the pig could utilise some of the D-isomer from a racemic mixture. The addition of a mixture of terramycin, streptomycin and penicillin did not influence the response to different supplements of tryptophan. Pigs on a diet deficient in tryptophan had thyroids larger than normal, but dressing percentage and sp. gr. of the carcase were not affected.—T. D. Bell.

1254

LARSON, N. L., HILL, E. G. (with WARMANEN, E.) **The intestinal microflora of young swine obtained by hysterectomy. Observations on chlortetracycline supplementation.** *J. Animal Sci.*, 1955, **14,** 674–687. [Hormel Inst., Univ. Minnesota, Austin.]

In a series of 3 experiments foetal pigs were obtained by hysterectomy. They were not allowed colostrum, and had no contact with other pigs. In each experiment one group got the basal ration and the other had the same plus a supplement of chlortetracycline. Faeces were sampled at intervals and at the end of the experiments, 69, 99 and 88 days for experiments 1 to 3, respectively, the pigs were killed and contents of duodenum, ileum, caecum and large intestine were also sampled. In all samples bacterial counts of total aerobes, anaerobes, *Bacterium coli*, enterococci, lactobacilli, clostridia, yeasts and proteus were made.

There were slight differences between the diets and the housing conditions in the 3 experiments, but the differences in bacterial counts were as great within experiments as between them. Similarly, no effect of the antibiotic on faecal bacterial counts was found. In pigs getting chlortetracycline clostridia in the ileum were suppressed.

In a fourth experiment the respiratory activity of faeces and intestinal contents of pigs which had been treated in the same manner as in the previous experiments was estimated. Chlortetracycline greatly reduced the oxygen uptake of the contents of the ileum and that of the faeces to a less extent.

1255

HARRINGTON, G. and TAYLOR, J. H. **The effect of antibiotic dietary supplements on the carcass measurements and dressing percentage of bacon pigs.** *J. Agric. Sci.*, 1955, **46,** 173–179. [Agric. Res. Counc., Sch. Agric., Univ. Cambridge.]

An analysis was made of data on carcase quality from 4 experiments with 402 bacon pigs in all.

There was no significant difference between carcase lengths of pigs on control diets and those of pigs on the same diets supplemented with aureomycin or penicillin. There was more variation between groups receiving different levels of penicillin than between control groups or groups receiving aureomycin. This variation in length was apparently associated with variation in growth rate, faster growing pigs having the shorter carcases.

There was no overall difference in backfat or belly thickness between control groups and those receiving either antibiotic.

Penicillin gave dressing percentages below those of the controls, but the difference was not statistically significant. Aureomycin gave dressing percentages significantly above those of groups receiving penicillin.

Diets containing animal protein gave higher dressing percentages than all-vegetable diets.

BOEGER, O., WESTERHOFF, W. and WINTER, A. G. Untersuchungen über Antibiotika aus höheren

Pflanzen. Schweinemastversuche mit den antimikrobischen Wirkstoffen der Kapuzinerkresse. [**Studies of antibiotics from higher plants. Pig feeding experiments with antimicrobial substances from nasturtium.**] *Naturwissenschaften*, 1955, **42**, 464. [Versuchsanst. Futterungsfragen, Wahn, Rheinland.]

In a 5-month experiment with 10 pigs of the Improved White Landschwein breed fed from 36 to 100 kg. on a ration of ensiled potatoes and beet slices, improved fodder beet, dried sugar beet leaves and 3/4 kg. coarsely ground cereals, one group had also 300 g. protein concentrate and the other group half as much plus 8·3 g. per 100 kg. bodyweight of Tromalyt, a preparation containing about 1 per cent. of the antibiotic substance of mustard oil type discovered in the nasturtium by Winter and Willike (*Naturwissenschaften*, 1952, **39**, 236).

The mean daily weight gains were 591 and 567 g., respectively, but the amounts of true protein per kg. weight gain were 405 and 347 g.; that is, Tromalyt gave a saving in protein of 14·3 per cent., compared with 22 per cent. in an experiment with procaine penicillin at the same place. Although the Tromalyt group did not look well, with rough coats and rather grey skin, there was no difference in carcase quality. Nasturtiums are easily grown and pigs eat them readily without ill effect. It is suggested that other plants containing mustard oils may have similar properties, and more extensive studies have been begun. (See Abst. 1299).

Taylor, J. H. and Gordon, W. S. **Growth-promoting activity for pigs of inactivated penicillin.** *Nature*, 1955, **176**, 312–313. [Agric. Res. Counc., Field Stat., Compton, Berks.]

In one experiment 4 groups each of 8 pigs were fed from weaning to 200 lb. liveweight on a diet supplemented with 15 g. procaine penicillin G per ton. For 3 groups the supplementary penicillin was inactivated by heat, by penicillinase or by contact with the salts of heavy metals. Active penicillin was given to the fourth group and a fifth control group received the unsupplemented basal diet. Pigs receiving active penicillin grew 9·7 per cent. faster than the controls and had a 6·6 per cent. better feed conversion efficiency; pigs receiving inactivated penicillin grew 5·9 per cent. faster than the controls and had a 3·0 per cent. better feed conversion efficiency.

In a second experiment 120 pigs were kept from weaning to 120 lb. liveweight and different groups received the basal diet alone or supplemented with 15 g. of either active or inactivated procaine penicillin per ton. Other groups were given the basal diet and received intramuscular injections of 0·5 mg. per kg. bodyweight daily of either active or inactivated procaine penicillin. In this experiment the inactive material produced an increase in rate and efficiency of growth, irrespective of the route of administration. In a comparable experiment inactivated aureomycin hydrochloride was found to produce no growth response. Over both experiments inactive penicillin produced 66 per cent. of the growth response achieved with active penicillin. It is suggested that this response may have been due to the thiol amino-acid penicillamine, which is a relatively stable end-product common to each of the 3 methods of inactivation employed.—I. A. M. Lucas.

1258

Lucas, I. A. M. and Calder, A. F. C. **Thyroxine, stilboestrol and antibiotics in rations for castrated male pigs.** *Brit. J. Nutrition*, 1955, **9**, 267–279. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Castrated male pigs were reared and fattened from 40 to 200 lb. liveweight, the control group on a basal ration containing white-fish meal, with 17 per cent. protein, up to 100 lb. liveweight, and then with 13·5 per cent. protein. The feed was given as a meal wet with twice its weight of water, 2·2 lb. per head being given at the start, rising to 7·7 lb. by the last week. Experimental groups were given the same, with supplements of: group 2, sodium L-thyroxine pentahydrate with stilboestrol; group 3, Aurofac 2A; group 4, procaine penicillin; group 5, Aurofac 2A and the hormones; group 6, procaine penicillin and the hormones.

During the growing period, 40 to 100 lb. liveweight, groups 3 and 4 grew 23 and 21 per cent. faster and efficiency of feed conversion was 14 and 15 per cent. better, respectively, than in controls. In group 2 rate of gain was only 4 per cent. and efficiency 3 per cent. better than in controls during this period. The efficiency and rate of gain of groups 5 and 6 were both 8 per cent. less than those of groups 3 and 4.

From 100 to 200 lb. liveweight the improvements in groups 3 and 4 were 6 and 4 per cent. for efficiency, respectively, and 7 per cent. for growth rate for both groups. The hormones given to group 2 improved both growth rate and efficiency by 8 per cent. There was no difference between groups 3 and 5, but group 6 was 8 per cent. more efficient and grew 6 per cent. faster than group 4.

From weaning to slaughter the antibiotics given to groups 3 and 4 improved rate of gain by 15 per cent. and efficiency by 8 per cent., while the hormones alone, in group 2, improved growth by 6 and efficiency by 4 per cent. In group 5 growth rate was no better than in group 3, but efficiency was 5 per cent. less; group 6 was 5 per cent. more efficient than group 4 though rate of gain was not

affected. There was no difference between the groups in dressing percentage or carcase measurements, except that in group 6 depth of fat over the eye muscle was reduced. The reasons for the different effects of the hormones in the growing and fattening periods are discussed.—T. D. Bell.

1259

BRAUDE, R., CAMPBELL, R. C., LUCAS, I. A. M., LUSCOMBE, J. R., ROBINSON, K. L. and TAYLOR, J. H. **Antibiotics and endocrine stimulants as promoters of growth in fattening pigs.** *Brit. J. Nutrition*, 1955, **9**, 191–196. [Nat. Inst. Res. Dairying, Univ. Reading.]

At 5 centres 154 pigs were used in a coordinated experiment designed to test the value of additions of L-thyroxine or L-thyroxine and stilboestrol to rations already containing either aureomycin or penicillin. In addition control groups of pigs were given diets containing neither antibiotic nor hormone.

At 3 centres pigs on the diet supplemented only with antibiotic grew faster than the controls, but at 2 centres there was no difference with antibiotic.

The addition of both thyroxine and stilboestrol to a ration not containing antibiotic gave a slight improvement in rate and efficiency of growth at one of 2 centres.

When thyroxine and stilboestrol were added to a diet already containing antibiotic at 2 centres there was no growth stimulation but at 2 other centres there was a significant improvement. At one centre, toxic signs were seen which were apparently associated with the feeding of stilboestrol, and it was therefore considered inadvisable to use this substance as a growth stimulant.

At 2 centres the addition of thyroxine alone to a diet containing antibiotic gave a slight improvement in rate and efficiency of growth, but at a third it did not.—I. A. M. Lucas.

1260

OLOFSSON, N. E. Kompletta kraftfoderblandningar för svin. [**Complete concentrate mixtures for pigs.**] *Kungl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 105, 1954, pp. 6.

The recommended standard concentrate ration for pigs (see Abst. 3955, Vol. 17) contained mixed grain, bran, meatmeal, fishmeal, hay meal, salts and vitamin D. A mixture now produced commercially differs from the above in that the grain is wholly or partly replaced by the remaining ingredients and sometimes contains antibiotic. Directions are given with this product for the amount of grain to be added according to the age of the pig to make up a suitable ration. Pigs fed on rations containing 90 or 95 per cent. mixed grain and the remainder concentrate, and on rations containing only grain and skimmed milk, 0·5 or 1·0 kg. milk per kg. grain, had similar gains in weight. The higher cost of the rations containing concentrate was considered to be compensated for by the decrease in work required.—A. Hepburn.

1261

BECKER, D. E., TERRILL, S. W., JENSEN, A. H. and NOTZOLD, R. A. **Levels of protein for pigs fed a controlled concentrate intake on alfalfa pasture.** *J. Animal Sci.*, 1955, **14**, 652–658. [Illinois Agric. Exp. Stat., Urbana.]

Trials were made in 2 seasons with pigs on alfalfa pasture from weaning to slaughter. The pasture was kept lush by frequent clipping. Groups of pigs were given concentrate mixtures containing 8·9, 9·0, 10·0, 12·0, 14·0 or 16·0 per cent. protein. The source of protein was solvent-extracted soya bean oilmeal, and the percentage was regulated by varying the proportions of this and ground yellow maize. The mixture contained antibiotics and vitamin B_{12}. Results were considered from weaning to 100 lb. and from 100 to 200 lb. liveweight.

In both trials the best growth rate and efficiency of feed conversion from weaning to 100 lb. liveweight were in the group getting 12 per cent. protein. There was a significant difference between the trials: on all protein levels growth rate was not as good in the second, but efficiency was greater.

From 100 lb. to slaughter there was no advantage of the higher levels of protein when pigs had had 12 per cent. protein during the first period. The performance of the pigs during the fattening period was influenced by the diet during the growing period. Thickness of back fat was not significantly affected.—T. D. Bell.

1262

RICHTER, K. and OSLAGE, H. J. Zur Frage der Fleischqualitat und ihrer Beeinflussung durch die Fütterung. [**Quality of meat and the effect of diet on it.**] *Züchtungskunde*, 1955, **27**, 99–113. [Inst. Tierernähr. Forschungsanst. Landwirtsch., Brunswick-Völkenrode.]

In the first study there were 4 groups, each of 8 pigs. In all groups the concentrate ration consisted of 1 kg. per head of a mixture of barleymeal, soya meal, fishmeal and minerals. The rest of the ration, given to appetite, consisted of steamed ensiled potatoes alone, or with ensiled "Diffusionschnitzeln" in the ratio 2 : 1 or 1 : 2, or of artichokes. At the end of the fattening period the pigs were fasted for 15 hr. and then slaughtered. Carcase quality was judged by a points system on colour, quality of meat, back fat, fat : flesh ratio, hams, abdominal fat and general impression. The water-binding capacity of the meat was estimated. The carcase was measured and different parts were weighed.

There was no important difference in carcase quality between the 4 groups. The highest total of points was given to the group which received 2 parts of potatoes to 1 of " Diffusionschnitzeln ". This group had meat of rather dark colour.

In the second study, by the same methods, there were 3 groups of 8 pigs. All received fresh steamed potatoes to appetite. The 1 kg. concentrates contained for different groups either 150 g. fishmeal and 150 g. soya meal, or 75 g. of each, or only 50 g. fishmeal to provide protein.

The low-protein group had a low points count for carcase quality, but there was little difference between the other groups. The low-protein pigs had pale-coloured meat of poor quality, and the meat gave up its water more readily than that of the other groups. The hams and abdominal fat were poorly developed.—D. Duncan.

1263

CALDER, A. **Fodder beet for pigs.** *Rhodesia Agric. J.*, 1955, **52,** 238–245. [Pig. Indust. Board, S. Rhodesia.]

Trials of the possibilities of growing fodder beet in Rhodesia are in progress. It is hoped that the crop will replace some of the maize at present used for fattening pigs.

With this object in view an experiment was made with 4 groups of pigs fattened from weaning to 200 lb. liveweight. Group 1 got a meal supplement gradually increasing in amount till each pig was receiving 3 lb. daily, at a liveweight of about 69 lb., and then got fresh chopped fodder beet to appetite in addition to the meal. The second group did not get fodder beet until, at about 115 lb. liveweight, meal consumption was 4·5 lb. daily. The meal was then reduced to 3 lb. and fodder beet was given to appetite. The meal supplement had 18·5 per cent. protein. Groups 3 and 4 were given an allowance of the same supplement and maize. The supplement was 22·2 per cent. of the ration under 100 lb. liveweight, 20·1 per cent. from 100 to 150 lb. and 16·7 per cent. over 150 lb. liveweight. Group 3 was allowed this ration to appetite, and group 4 got a maximum of 5 lb. daily. The saving in meal was 198 and 128·6 lb. by groups 1 and 2, respectively, compared with group 3, and 178 and 107 lb. compared with group 4. Judged by standards for thickness of back fat and firmness of fat the pigs fattened with fodder beet were superior to those getting maize.—T. D. Bell.

1264

FIRTH, J. A. and JOHNSON, B. C. **Sewage sludge as a feed ingredient for swine and poultry.** *J. Agric. Food Chem.*, 1955, **3,** 795–796. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Baby pigs, 2 to 3 days old, were given a diet of synthetic milk. One group of 3 received daily 0·8 μg. vitamin B_{12} per kg. bodyweight intramuscularly and a second group of 4 received dry activated sewage sludge, containing from 4·0 to 7·5 μg. vitamin B_{12} per g., at a level of 10 per cent. of the dry matter of the diet. At this level the sludge had a detrimental effect on growth. With 5 per cent. of sludge growth was comparable with that of pigs on the basal ration with vitamin B_{12}.

In similar experiments with chickens levels of 2 and 10 per cent. sludge produced in 4 weeks growth responses 8 per cent. higher than that from the basal ration supplemented with 50 μg. vitamin B_{12} per kg. diet. Feed efficiency also was considerably improved.—J. S. Thomson.

1265

NOLAND, P. R., STEPHENSON, E. L. and DIGGS, B. **The value of several supplements as sources of unidentified growth factors for swine.** *J. Animal Sci.*, 1955, **14,** 628–635. [Dept. Animal Indust., Univ. Arkansas, Fayetteville.]

In 2 trials with weanling pigs the addition of 2 per cent. of the residue of cod liver after enzymic digestion increased growth rate when oxytetracycline (terramycin) was also present. In one trial 3 per cent. fish solubles increased growth, but in another no response was obtained with 2 per cent. of the same solubles. The basal ration contained soya bean meal, but when part of this was replaced by cottonseed meal the response to fish solubles was greater. Oxytetracycline also improved growth rate when added to the basal ration. Other supplements tried, replacing soya bean meal on an equivalent protein basis, were fishmeal, a fermentation product, and the water- and fat-soluble fractions of the cod liver residue. None of these alone or in combination produced any growth response, but when part of the soya bean meal was replaced by cottonseed meal the fermentation product did improve growth rate slightly.—T. D. Bell.

1266

TSCHIDERER, K. Schweinefütterungsversuch mit " Wal-Sol " und Magermilch als tierische Eiweissquellen. [**Pig feeding experiments with " Wal-Sol " and skimmed milk as sources of animal protein.**] *Bodenkultur*, 1954, **8,** 39–42. [Schweine-Versuchsanst., Schwechat, Vienna.]

In a trial with 2 groups of 7 pigs of the German Edelschwein breed fed for 133 days, from about 19 to about 100 kg. liveweight, on a ration of cereals and skimmed milk (details given), a supplement of 1·5 per cent. " Wal-Sol " (dried whale solubles, crude protein content 78·4 per cent.) gave smaller final weight, mean daily weight gain and feed efficiency than 3 per cent. " N-yeast ". There was no difference between the carcases at slaughter except that 3 of the pigs given whale solubles had firmer back fat than those given yeast.—W. M. Deans.

1267

LEVIN, N. Otkorm svinei na maslodel'nykh zavodakh. [**Fattening pigs at butter factories.**] *Mol. Prom.*, 1955, **16,** No. 3, 39–40. [Belglavmasloprom.]

1268

KLINE, E. A. and HAZEL, L. N. **Loin area at tenth and last rib as related to leanness of pork carcasses.** *J. Animal Sci.*, 1955, **14,** 659–663. [Iowa State Coll., Ames.]

The area of muscle of the loin (eye muscle) at the tenth and the last ribs on each side, the percentage lean cuts and the percentage loin of 23 carcases of 8 breeds and crosses were studied. No difference between sides was found. The area of the eye muscle at the last rib was 0·43 sq. in. greater than at the tenth rib. There was no difference between the correlation of percentage lean cuts or percentage loin and area of eye muscle at the tenth and the last rib. The additional accuracy obtained by measuring eye muscle at different locations in calculating percentage lean cuts or area of loin was too small to be worth while.

GOATS, RABBITS AND OTHER MAMMALS

1269

NORDFELDT, S., MELIN, G. and THELANDER, B. Försök med antibiotika i fodret till pälsdjur. [**Experiments with antibiotics in the ration of fur animals.**] *Kungl. Lantbrukshögsk. Statens Husdjursförsök Särtryck* No. 107, 1954, pp. 24. English summary.

The effects of aureomycin, terramycin, bacitracin, penicillin and vitamin B_{12} on pregnant and nursing mothers of silver fox, blue fox and mink and on their kits up to pelting time were observed. Results varied considerably. Weaned silver fox and blue fox kits fed on an all-vegetable diet did not grow normally and the addition of antibiotics or vitamin B_{12} had no effect. Fresh meat or fish was needed for good growth and antibiotics gave little improvement but were beneficial to suckling young. Procaine penicillin prevented diarrhoea and weight loss in mink kits fed for several days on tainted fish.—A. Hepburn.

1270

ABRAMOV, M. D. and POVETSKII, I. G. Normy i ratsiony dlya vzroslykh golubykh pestsov. [**Standard diets and rations for adult blue Arctic foxes.**] *Karakul. i Zver.*, 1955, **8,** No. 1, 26–33. [All-Union Sci. Res. Lab. Fur-bearing Animals and Pantiferous-Deer Management.]

The generally accepted standard rations for Arctic foxes were found in practice to be above requirements and they do not take into consideration biological and seasonal variations. For instance, the standard recommended for the entire period October to March is 700 Cal. daily, but at the Saltykov Animal State Farm foxes receive not more than 610 Cal. from October to December, 550 Cal. in January and 510 Cal. in February and March, with perfectly satisfactory results.

From practical experience on a number of state farms revised standards were evolved, the allowance varying from 525 to 650 Cal. daily according to the season. During the first half of pregnancy 650 Cal. was allowed and during the second 700 Cal. Meat and fish supply 50 to 70 per cent. of the energy, dairy products 5, grain 18 to 35 (a higher proportion of grain being given in summer than in winter and autumn, least of all in spring), vegetables 3 to 5, and fish oil 2 all the year round. During pregnancy the percentages are 65, 10, 18, 5 and 2. All these figures are averages which may be altered according to the health of the animals, seasonal or climatic variations, or liveweight.

H. Scherbatoff.

1271

BELYAEVA, V. A. Rol' ovoshchei v pitanii norok. [**The role of vegetables in mink nutrition.**] *Karakul. i Zver.*, 1955, **8,** No. 1, 40–44. [Sci. Res. Inst. Rabbit and Animal Management.]

The inclusion of green vegetables in the ration of minks had no bad effect on fur growth, but did have a detrimental effect on the digestibility of the ration and on the utilisation of protein. It is concluded that the amount supplied should not exceed 20 g. daily.—H. Scherbatoff.

1272

TSIREL'SON, N. B. Vliyanie polnotsennogo kormleniya krolikov na razvitie nasledstvennykh kachestv potomstva. [**The effect of improved feeding of rabbits on the development of hereditary qualities in the progeny.**] *Agrobiologiya*, 1954, No. 6, 138–139. [Moscow Technol. Inst. Meat and Milk Indust., Dept. Raising Agric. Animals and Special Zootech.]

The result of improved feeding of rabbits was apparent in the third generation, which showed a considerable advance on the second and first generations. This improvement showed itself in increased live- and deadweight, faster growth, larger size, better developed internal organs and increase in the amount of down by 6 to 7 per cent.

H. Scherbatoff.

POULTRY

GROWTH AND FATTENING

1273

HOHLS, H. W. Der maximal mögliche tägliche Eiweissansatz von Leghornküken verschiedenen Alters. [**Maximum possible daily deposition of protein by Leghorn chicks at different ages.**] *Arch. Geflügelk.*, 1955, **19**, 327–353. [Bundesforschungsanst. Kleintierzucht, Celle.] English summary.

Some of the results discussed appeared in an earlier paper (Abst. 5854, Vol. 25). From these experiments and others it was concluded that the protein intake of chickens given practical rations to appetite often exceeded their capacity to deposit body protein. No way is known of increasing this capacity, which was not improved by antibiotics. It is suggested that poultry feeding costs may be reduced by selection of good converters of protein and by giving supplements to improve general efficiency of use of feed.—D. Duncan.

1274

HOHLS, H. W. **The rate of daily feed consumption, the daily maximum protein anabolism and their importance concerning the evaluation of feeding experiments with antibiotic supplements.** *Poultry Sci.*, 1955, **34**, 717–724. [Bundesforschungsanst. Kleintierzucht, Celle, Germany.]

When feed eaten provides more protein than can be retained the effects of penicillin may be negligible. This is often the case in experiments with antibiotics. Before the effects of an antibiotic can be evaluated it should be ascertained that feed intake is not excessive.—T. D. Bell.

1275

FANGAUF, R., KLEIN, F. W. and BARLÖWEN, G. v. Die Höhe des Proteinanteiles im Aufzuchtfutter für Hühnerküken. [**Level of the protein component in rearing rations for chicks.**] *Arch. Geflügelk.*, 1955, **19**, 358–368. [Versuchsanst. Kleintierzucht, Kiel-Steenbek.] English summary.

Twenty groups of 30 day-old New Hampshire chicks were used in this 8-week trial. There were 4 main divisions : animal protein only, and animal protein and vegetable protein in the ratio 2 : 1, 1 : 1 and 1 : 2, supplied by cod fishmeal, crude protein 66 per cent., and extracted soya grits, crude protein 44 per cent. Within each division there were 5 groups, for which the rations were adjusted to supply 14, 16, 18, 20 and 22 per cent. crude protein. All groups had 3 per cent. of a mineral mixture, calcium carbonate 40, calcium phosphate 40, salt 20 and manganese sulphate 0·025 per cent., and vitamins, vitamin A 4000 I.U., vitamin D_3 400 I.U., vitamin B_2 2·5 mg. and pantothenic acid 8 mg. per kg. diet. The rest of the ration, from 69 to 92·5 per cent., was a mixture of equal parts of ground wheat, ground maize, ground barley and wheat bran. The food was given dry and was available all the time. The results are presented in tables. Only 1 chick died of the 600.

Total feed consumption was not significantly affected by the nature of the protein but did increase with the crude protein content of the diet up to 20 per cent. and then fell. Weight at 8 weeks and weight gain behaved similarly. The best gain was with 20 per cent. protein of which 2/3 was animal. Feed efficiency, measured both by total nutrients and by feed consumed per unit gain, likewise varied little with the nature of the protein, and was best with 16 per cent. protein, all animal, and next best with half animal, half vegetable. Particulars of protein consumption also are tabulated and show that 22 per cent. crude protein is definitely wasteful. Least cost per kg. gain was found with 16 per cent. protein, all animal or half animal, half vegetable ; next came 18 per cent. protein, with animal and vegetable in the ratio 1 : 2.

Practical recommendations are that laying and breeding pullets should be reared on a 16 per cent. protein ration containing fishmeal 4·6 and soya grits 6·9 per cent., and that for fattening the ration should contain 20 per cent. protein (fishmeal 10·8 and soya grits 8·2 per cent.).—W. M. Deans.

BENTON, D. A., SPIVEY, H. E., HARPER, A. E. and ELVEHJEM, C. A. **Factors affecting the growth of chicks on amino acid diets.** *Arch. Biochem. Biophys.*, 1955, **57**, 262–263. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Day-old chicks were given a synthetic basal ration containing adequate amounts of amino-acids instead of protein. To this was added one of the following supplements : casein 5 or 10 per cent. ; gelatine 5 per cent. ; casein 18 and gelatine 10 per cent. ; zein 5 per cent. ; fibrin 5 per cent. ; acid or alkaline hydrolysates of gelatine.

The growth stimulation in 13 days given by 5 per cent. casein was only slightly inferior to that given by 10 per cent. Gelatine 5 per cent. was twice as good as casein 5 per cent., and fibrin was as good as casein ; zein was intermediate. Between them zein and gelatine have deficiencies of all the essential amino-acids, and the difference in growth stimulation seemed to be related to their proline contents, but the addition of 1 per cent. proline to the basal ration, already containing 0·5 per cent.,

stimulated growth only slightly. The acid hydrolysate of gelatine was as effective as the intact gelatine, but the alkaline hydrolysate was not so effective, though growth was better when it was added to the basal ration than in control birds. The high level of casein and gelatine combined was scarcely better than 5 per cent. gelatine alone. The growth substance in acid hydrolysates of gelatine is being investigated.—T. D. Bell.

SHAW, R. B. and NIGHTALL, E. W. **The influence of protein levels on poultry production.** *J. Sci. Food Agric.*, 1955, **6**, 390–401. [Univ. Nottingham Sch. Agric., Sutton Bonington, Loughborough, Leics.]

During 3 years, trials were made with growing chickens and laying pullets to compare rations with no protein supplement, rations with a supplement of bean meal, and normal rations with fishmeal. The crude protein contents of the laying rations were 10, 12 and 12 per cent. The birds had access to pasture when they reached 10 days of age. At 24 weeks old they were transferred to houses with slatted floors on a grass run for the laying period. Growth rates to 24 weeks and egg production during a laying season of 48 weeks were recorded.

On the fish meal ration growth rate was best, and the birds began to lay 2 to 3 weeks earlier. Egg production was also best on this ration, but it was satisfactory on all the rations. The extra production of the birds getting animal protein offset the extra cost of the ingredients. In all respects the group getting bean meal was least satisfactory.

In trials comparing laying hens folded on fresh pasture every day and receiving similar rations except that fishmeal was excluded from one group, the birds on the ration without fishmeal gave egg productions, in seasons of 47, 48 and 39 weeks, of 181·0, 191·6 and 130·9 on a hen-day basis. For the other group the egg production was 175·5, 183·7 and 150·2. The protein contents of the rations were 1 per cent. higher in the birds getting the animal protein. It was clear from the foregoing trials that on pasture satisfactory egg production could be maintained without fishmeal.

Finally, trials were made with laying pullets in batteries, receiving rations with or without 7 per cent. fishmeal. In all 3 trials egg production was much better when the fishmeal was given, and profits were greater. In 2 of the trials, the groups without fishmeal produced satisfactory numbers of eggs ; in the other trial it became obvious after 14 weeks that the birds were doing badly, and 3·5 per cent. fishmeal was added to the ration. Thereafter they produced almost as many eggs as the birds in the fishmeal group.—T. D. Bell.

CARVER, D. S., RICE, E. E., GRAY, R. E. and MONE, P. E. **The utilization of fats of different melting points added to broiler feed.** *Poultry Sci.*, 1955, **34**, 544–546. [Swift and Co. Res. Labs., Chicago, Ill.]

Three experiments are reported on the effect on growth to 4 weeks and feed conversion of adding tallow, hydrogenated tallow, hydrogenated tallow fatty acids or oleic acid at a 3 per cent. level to the basal ration of day-old chicks. For 4 days during the experiment the amount of food eaten was accurately measured and the faeces were collected and analysed to estimate the absorption of the added fats.

Growth to 4 weeks was not affected by any of the fats. In one experiment feed conversion was improved by 6 per cent. with all fats except hydrogenated tallow. Hydrogenated tallow and hydrogenated tallow fatty acids were not well absorbed but unmodified tallow was, to the extent of 81 to 100 per cent. Inability to hydrolyse the hydrogenated product cannot explain the poor absorption.

SCHNEIDER, A. J., BOHREN, B. B. and ANDERSON, V. L. **The effect of restricted feeding on several genetically controlled characters in the fowl.** *Poultry Sci.*, 1955, **34**, 691–702. [Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Two groups of New Hampshire and Single Comb White Leghorn chicks were given a starter ration containing 25·15 per cent. protein. To one group, the fast-growing group, this was given to appetite to 8 weeks of age ; then a growth ration containing 18·8 per cent. protein was given to 22 weeks of age. The other group, the slow-growing group, got the starter mash plus crimped oats, restricted to 2 hours' feeding daily after 6 weeks. After 8 weeks the same restriction was imposed, but the starter mash was replaced by the same growth mash as was given to the fast group. For the slow group the scale of feeding was further reduced at 12, 16 and 24 weeks of age, and they continued on the same ration to 28 weeks of age. From hatching to 28 weeks of age the feed intake of the slow group was 79 per cent. of that of the fast group to 22 weeks of age, and the total protein was 15·86 per cent. of the ration.

At the end of the growing period each group was divided into 2, half of each group getting a normal laying ration with 16·96 per cent. protein, and the other a high-protein laying ration with 21·34 per cent. protein, to appetite. A group of New Hampshires only got the starter mash to appetite to 8 weeks of age, the grower mash to 22 weeks of age, and then were divided and treated as the first 2 groups. The whole experiment lasted 60 weeks.

During the growing period growth was retarded in the restricted group, but after 4 weeks on either laying ration the difference disappeared ; maturity was retarded by 2 to 4 weeks ; there was no effect on mortality. In the laying period, from 28 to 60 weeks of age, mortality was lower in those groups in which feed had been restricted during the growing period. During the first 4 laying weeks egg size in the slow groups was less, but after that there was no difference. Fast-growing birds laid more eggs during the first part of the laying period and slow-growing more during the last part, so that over the whole laying period there was no difference between fast- and slow-growing birds in the total number of eggs produced. Significantly more eggs of hatchable size were produced by the slow growers. They were also slightly better in fertility and hatchability.

The protein level of the laying ration did not affect bodyweight, mortality, size or number of eggs, or number of eggs of hatchable size, but the high protein reduced fertility, hatchability and hatch of total eggs set. The response of both breeds was the same.—T. D. Bell.

KRATZER, F. H., VOHRA, P., ATKINSON, R. L. and DAVIS, P. N. **Treatment of dried whey with various solvents ; effects upon the growth of chicks.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89**, 273–274. [Dept. Poultry Husb., Univ. California, Davis.]

The addition of untreated dried whey to a synthetic ration for chickens gave only a small growth response or none. When the whey was extracted with 70 per cent. methanol, ethanol or *iso*propanol the extract and the extract plus residue were more active than the original whey ; the residue alone was only slightly better than the original dried whey. Dried whey treated with water in an amount equivalent to that of the solvent-water mixture increased the rate of growth above that with the original untreated dried whey. The addition of water to the basal ration had no effect.

CARPENTER, K. J., ELLINGER, G. M. and SHRIMPTON, D. H. **The evaluation of whaling by-products as feeding-stuffs.** *J. Sci. Food Agric.*, 1955, **6**, 296–304. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Studies were made on 6 samples of whalemeat meal and 2 samples of condensed whale solubles. Estimation of the proximate components and selected minerals of these 8 by-products showed that the meatmeals were low in ash, in particular Ca and P, and that condensed whale solubles contained negligible amounts of Ca ; the level of chlorides was not unduly high in any of the meals but was higher in both samples of solubles. Selected vitamins and amino-acids were estimated microbiologically ; the condensed whale solubles were inferior to the meatmeals as sources of lysine, cystine, methionine, tryptophan, riboflavin, pantothenic acid and vitamin B_{12}. The by-products were tested as protein supplements for starting chicks ; of 936 chicks used in the study, 33 died. The calculated gross protein values, relative to standard casein = 100, from each trial gave values of 95 to 105 per cent. for the meatmeals and 55 to 60 per cent. for the condensed whale solubles. Toxicity tests also were made with the condensed whale solubles, with chicks from 1 to 4 weeks of age ; there was no evidence of toxicity when the solubles formed up to 15 per cent. of the ration.

1282

WILDER, O. H. M., OSTBY, P. C. and GREGORY, B. R. **The use of chicken feather meal in feeds.** *Poultry Sci.*, 1955, **34**, 518–524. [Div. Animal Feeds, Amer. Meat Inst. Found., Univ. Chicago, Ill.]

The feather meals used had the following average percentage composition : crude protein 87, pepsin-digestible protein 75, tryptophan 0·56, lysine 1·34, methionine 0·51, ash 3·16 ; cholesterol 667 mg., choline 612 mg. and vitamin B_{12} 38·6 μg. per lb.

Three experiments are reported in which feather meal was added at levels varying from 2·4 to 6·2 per cent. of the total protein of a low-protein ration, chiefly of maize and soya bean oilmeal, for chickens fed from 2 days old up to 6 or 8 weeks. Comparisons were made with bloodmeal and meat-and-bone scrap as supplements. In some experiments the feather meal was supplemented with L-lysine or vitamin B_{12}.

The data from the 3 experiments showed that feather meal alone did not completely replace an equal amount of soya bean oilmeal in the basal ration, probably owing to its deficiency in lysine. The addition of lysine improved its value. Satisfactory growth and feed utilisation were obtained when the feather meal was combined with either bloodmeal or meat-and-bone scrap which remedied the lysine deficiency. The further addition of vitamin B_{12} to some of the rations produced a slight increase in growth rate.—J. S. Thomson.

PALAFOX, A. L. and ROSENBERG, M. M. **A comparison of Hawaiian meat and bone meal, soybean oil meal, and herring meal in chick starter rations.** *Hawaii Agric. Exp. Stat. Tech. Bull.* No. 28, June 1955, pp. 15.

Meat-and-bone meal is a by-product of the local meat industry and contains 46 to 50 per cent. protein. Four experiments are reported on its

value for growing chickens in conjunction with soya bean oilmeal and herring meal.

The results showed that meat-and-bone meal, which is cheaper than soya bean oilmeal, could be incorporated in the ration up to 6 weeks of age at a level of 16 to 18 per cent. without loss of feed efficiency.—J. S. Thomson.

McDonald, M. W. and McClymont, G. L. **High energy chicken rations based on crushed wheat and meatmeal.** *Agric. Gaz. N.S.W.*, 1955, **66,** 265–269. [Poultry Exp. Stat., Seven Hills.]

Results are reported of 6 experiments with chickens to demonstrate that high-energy rations based on wheatmeal and high-protein meatmeal, though dearer, are more economical than standard-type rations containing bran and pollards, in that less feed was consumed per lb. weight gain. A source of B vitamins, such as buttermilk powder, and of manganese, to replace those in milling offals is required.—J. S. Thomson.

1285

Fangauf, R., Klein, F. W. and Barlöwen, G. v. Binsenmehl als Geflügelfutter. [**Bulrush meal as a feed for poultry.**] *Arch. Geflügelk.*, 1955, **19,** 374–379. [Versuchsanst. Kleintierzucht, Kiel-Steenbek.] English summary.

This trial was suggested by the facts that bulrushes (*Scirpus lacustris*, L.) are eaten by cattle and that fishermen in Finland give cut-up dried remnants from weaving to their hens along with reindeer moss and thereby get more eggs in winter.

The dry matter of fresh bulrushes was found to contain 17 or 18 per cent. crude protein. The dry matter of the bulrush meal amounted to 94·2 per cent., consisting of ash 37·7, crude protein 12·7, fat 1·7, fibre 15·2, N-free extract 26·9 ; it was thus much poorer in nutrients than green alfalfa meal, except in carotene, 144 mg. per kg. dry matter. This suggested a trial with bulrush meal replacing alfalfa meal.

Three groups of 30 day-old New Hampshire chicks were fed for 8 weeks on the usual Steenbek ration of ground maize 30, ground wheat 30, wheat bran 15, alfalfa hay meal 3, dried yeast 3, cod fish-meal 8, soya grits 8, calcium carbonate 1·2, calcium phosphate 1·2, salt 0·6, manganese sulphate 0·025 per cent. and a mixture supplying vitamins A and D, or the same with bulrush meal replacing the alfalfa meal, or the same with 6 per cent. bulrush meal and less maize, wheat and bran. The feeds were given as a mash available all day.

With 3 per cent. bulrush meal feed consumption was increased, but not with 6 per cent. The final mean weights on the assumption of a 50 : 50 ratio of the sexes were 600·4, 690·8 and 579·4 g., respectively. Feed efficiency, measured by total nutrients consumed per 100 g. gain, was 10 per cent. greater with 3 per cent. bulrush meal than with the other rations.

It was concluded that bulrush meal can replace alfalfa meal in the rearing of chickens, but should not exceed 4 per cent. of the ration.—W. M. Deans.

1286

Burton, H. W. **Sorghum doesn't harm chickens.** *Queensland Agric. J.*, 1955, **80,** 221–224.

Experiments with day-old cockerels showed that large amounts of sorghum, up to 60 per cent. of the ration, could be given without affecting growth rate. Feed efficiency was reduced, but this was offset by the lower cost of the sorghum compared with wheatmeal. A ration of 40 per cent. sorghum and 20 per cent. wheat was the most economical. Mortality rate was not affected.—J. S. Thomson.

1287

Arscott, G. H., Johnson, L. E. and Parker, J. E. **The use of barley in high-efficiency broiler rations. 1. The influence of methionine, grit and stabilized animal fat on efficiency of utilization.** *Poultry Sci.*, 1955, **34,** 655–662. [Dept. Poultry Husb., Oregon State Coll., Corvallis.]

In 2 experiments barley replaced 25, 50 or 100 per cent. of the yellow maize in rations for fattening broilers from hatching to 9 weeks old. In the first experiment supplements of 0·05 per cent. DL-methionine with or without grit were given, and in the second 4 or 8 per cent. fat as stabilised prime tallow.

In both experiments substituting 25 per cent. barley gave growth and efficiency of feed conversion comparable to the results on the all-maize ration. No benefit was gained from the supplement of DL-methionine at any level of barley, and the addition of granite grit was of no value. In the second experiment 4 or 8 per cent. fat improved growth rate and efficiency on 25 and 50 per cent. barley to the levels obtained with the all-maize ration, but the results on 100 per cent. barley did not compare favourably with those of the other groups. On the all-maize ration with 8 per cent. added fat feathering was poor, but this was not so when at least 25 per cent. of the maize was replaced by barley. Efficiency, but not growth rate, was slightly improved by the addition of fat to the maize ration.—T. D. Bell.

1288

West, J. W. **Cottonseed meal as a substitute for soybean oil meal in poultry rations.** *Poultry Sci.*, 1955, **34,** 547–553. [Dept. Poultry Husb., Mississippi Agric. Exp. Stat., State Coll.]

Two trials were made with New Hampshire chickens fattened for the broiler market, and one

with Broad Breasted Bronze turkeys getting a starter ration. Replacement of soya bean oilmeal by cottonseed meal was investigated. Both the meals were solvent extracted, and the cottonseed meal was free from gossypol. The broiler ration contained 20 per cent. protein, and the turkey starter ration 24 per cent. The basal rations were complex mixtures, with vitamin, mineral, antibiotic and arsonic acid supplements. The oilseed represented up to 20 per cent. of the starter and up to 25 per cent. of the broiler ration, and within this range the cottonseed meal and soya bean oilmeal were varied so that all combinations of the two were tested.

It was found that cottonseed meal could replace up to 80 per cent. of the soya bean meal satisfactorily, but when only cottonseed meal was given growth rate and efficiency of feed conversion were depressed, though in one of the tests with broilers this effect was not so clear as in the other. The meals together in any proportion gave better growth rate than either meal alone, which suggested that there was a complementary relationship.

Limited observations on carcase quality and uniformity did not show any specific effect due to cottonseed meal.—T. D. Bell.

1289

ROSENBERG, M. M. **B-grade molasses in starter, grower, and layer rations for chickens.** *Hawaii Agric. Exp. Stat. Bull.* No. 109, July 1954, pp. 26.

The results are reported of 7 feeding trials with chickens, cockerels and laying pullets to determine to what extent B-grade molasses and bagasse pith could replace yellow maizemeal in the diet. In most of the diets the levels of herring meal and soya bean meal were adjusted to replace the protein lost when molasses was substituted for maize.

Molasses was tolerated even when all the maize was replaced, so that B-grade molasses would be useful as an emergency carbohydrate feed. Efficiency of feed conversion fell as the level of molasses rose. In starter rations the most economical level was between 22 and 33 per cent. of the ration. In the trials with cockerels from 6 to 13 weeks the best results were obtained with levels of 17 to 18 per cent. With laying pullets levels up to 24 per cent. did not affect egg production, but feed consumption rose steeply at higher levels. Bagasse pith adversely affected growth of chickens and cockerels at levels of 4 to 9 per cent. of the ration.

J. S. Thomson.

1290

MORRISON, A. B., SCOTT, M. L. and NORRIS, L. C. **Evidence for an unidentified mineral required by the chick.** *Poultry Sci.*, 1955, **34**, 738–740. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

A mixture of maize distiller's solubles, fish solubles, grass juice, a dried whey product and penicillin mycelium meal, substances believed to contain an unknown growth substance for chickens, was added to a purified complete diet and given to chicks from hatching to 4 weeks of age. Another group of chicks got the purified ration plus the neutralised ash of the mixture of supplements given to the first group. A control group got the purified ration only. Weights at 4 weeks in 2 experiments on the diets in the above order were 445, 442; 402, 411; and 342, 330 g. These results indicate that at least some of the unidentified substance was contained in the ash.

Addition of minerals other than those contained in the basal ration, increase in the amounts of minerals already present, change in the Ca : P ratio and the addition of chlortetracycline (aureomycin) did not stimulate growth beyond that of controls.—T. D. Bell.

1291

PETERSEN, C. F., WIESE, A. C. and PAPPENHAGEN, A. R. **Unidentified chick growth factors. 1. Purified assay diet and crude supplement response.** *Poultry Sci.*, 1955, **34**, 673–678. [Dept. Poultry Husb., Univ. Idaho, Moscow.]

A purified diet made up of alpha-(soya bean) protein, DL-methionine, glycine, soya oil, minerals, vitamins, cerelose and penicillin, in which the cerelose and alpha-protein were varied to give rations of 20, 24, 28 and 32 per cent. protein, was tested with chickens from hatching to 4 weeks old. It was found to support satisfactory growth and maintain good health at all levels of protein. To the purified rations were then added substances thought to contain unidentified growth factors. Growth was stimulated by herring meal, sardine fish solubles, a 50 per cent. lactose dried whey product, Biopar C [not further described], and a defatted liver residue. Combinations of these supplements did not give any greater stimulus than the substances separately, and it is suggested that the New Hampshire chickens used in these trials, from hens reared on a standard breeder mash containing 25 per cent. fishmeal and kept on deep litter, may have had sufficient reserves of some growth factors which, when combined with others, have been shown to cause greater growth response.—T. D. Bell.

1292

CAMP, A. A., CARTRITE, H. T., QUISENBERRY, J. H. and COUCH, J. R. **Further information concerning unidentified chick growth factors.** *Poultry Sci.*, 1955, **34**, 559–566. [Texas Agric. Exp. Stat., Gonzales.]

Experiments are described in which day-old White Rock chicks were given a complete ration

with the addition of supplements which were thought to contain unidentified growth factors. Weights of birds at 10 weeks of age, efficiency of feed utilisation, and mortality were recorded.

Supplements of fish solubles, dried whey, fermented whey, hydrolysed whey and an antibiotic fermentation product all stimulated growth. The factor in dried and fermented whey appeared to be different from that in fish solubles and the antibiotic fermentation product. Combinations of the supplements thought to contain the different factors stimulated growth more than any single supplement. Hydrolysed whey may have contained a third factor, but the extra stimulation of growth when it was added to the other supplements may have been due to the increase of energy in the ration.—T. D. Bell.

WEST, J. W. and HILL, J. E. **Protein requirement of broilers as influenced by antibiotics.** *Poultry Sci.*, 1955, **34,** 628–634. [Mississippi Agric. Exp. Stat., State College.]

Eight trials were made in which basal rations containing 16, 18, 20, 22 or 24 per cent. protein were given to chickens of broiler type from hatching to 9 weeks of age. The basal rations were supplemented with aureomycin, terramycin or bacitracin, 10 g. per ton feed, or procaine penicillin, 2 g. per ton feed. The best growth rate and efficiency of feed conversion were obtained on the ration containing 18 per cent. protein and any of the antibiotic supplements: without antibiotics at least 20 per cent. protein was necessary to produce comparable results. Mortality was reduced when antibiotics were given.—T. D. Bell.

1295

MORENG, R. E., BOLIN, D. W., BRYANT, R. L. and GOSSLEE, D. G. **The influence of environment, diet and mode of administration on the response of chicks to antibiotics.** *N. Dakota Agric. Exp. Stat. Bull.* No. 398, June 1955, pp. 11.

Achromycin, bacitracin or aureomycin given by mouth to chicks, 1 week old, improved growth and efficiency of feed conversion in trials lasting 4 and 6 weeks. Subcutaneous implantation of bacitracin at the base of the head depressed growth, and the depression was less when penicillin was given by mouth. Change of environment from batteries to pens did not affect the response of the birds to the antibiotics. The responses obtained in old and new environments in 4 trials were not consistent, and no conclusion could be drawn.—T. D. Bell.

1296

RICHTER, K. and GERLACH, G. Kükenaufzuchtversuche mit gestaffelten Fischmehlgaben und dem antibiotischen Beifuttermittel "Entan". [**Chick rearing tests with graded amounts of fishmeal and the antibiotic supplement "Entan".** *Arch. Geflügelk.*, 1955, **19,** 354–] 357. [Inst. Tierernährung Forschungsanst. Landwirtsch., Brunswick-Völkenrode.] English summary.

Two trials with 14-day-old Brown Leghorn chicks are reported. In the first, 3 groups of 50 were fed for 7 weeks on a basal ration of ground barley 25, ground oats 25, ground maize 20, wheat bran 10, cod fishmeal 6, extracted soya grits 9, dried yeast 2, charcoal 1 and a 7 : 3 mixture of calcium carbonate and phosphate 2 per cent., or the same with 0·5 per cent. Entan, a preparation containing terramycin and vitamin B_{12}, or a ration with fishmeal only 2, ground oats 24, soya grits 14 and the other ingredients as before, with 0·5 per cent. Entan. Mean final weights were 649·4, 708·9 and 696·7 g., respectively; efficiency of use of feed was about 20 per cent. higher in the groups given Entan, and mortality was about 2 per cent., as against 11·8 per cent. in the control group.

In the next year there were 4 groups of 65 chicks and the trial lasted 8 weeks. The basal ration (group 1) contained barley 39, oats 30, no maize, dried yeast 3 and the other ingredients as before. Group 2 had the same with 0·5 per cent. Entan. Group 3 had fishmeal 4·5, barley 38·5, soya grits 11 and the rest as before, with 0·5 per cent. Entan. Group 4 had fishmeal 3, barley 38, soya grits 13, and the rest as before, with 0·5 per cent. Entan. Mean final weights were 730·1, 815·6, 770·8, 762·7, respectively. Efficiency was greater and mortality less when Entan was given, but the differences were less striking than in the first trial.

1297

AMSCHLER, J. W., NOWAK, H. and PAMMER, H. Gänsespätmast mit Aurofac-2A und Fortafeed mit verschiedenen Mineralstoffgaben unter besonderer Berücksichtigung der Lebergewichte. [**Late fattening of geese with Aurofac-2A and Fortafeed with different amounts of minerals, with special reference to liver weight.**] *Bodenkultur*, 1954, **8,** 43–49. [Inst. Tierzucht, Hochsch. Bodenkultur, Vienna.]

Results are tabulated of a 4-week trial, in October-November 1953, with 8 groups each of 60 geese in their first year, imported birds of the Jugoslav

breed, of a mineral mixture, Aurofac-2A or Fortafeed, singly, in pairs or all 3 together, as supplement to a basal ration of ground barley, ground maize, flaked oats and dried skimmed milk. The mineral mixture, of 3 parts calcium carbonate, 1 part salt and 1 part antimony trisulphide, was given at the rate of 30 kg. per 1000 kg. feed; Aurofac-2A, 1·360 kg., supplying 10·8 g. aureomycin, per 1000 kg.; and Fortafeed, a low-protein substitute for yeast containing residues from riboflavin and aureomycin manufacture, citrus meal, extracted soya bean meal, liver meal and diatomaceous earth and guaranteed to supply riboflavin 2, pantothenic acid 4, nicotinic acid 9, choline chloride 10 and folic acid 0·06 mg. per lb. at least, 1·330 kg. per 1000 kg.

Mean initial weight was about 3·4 kg. Mean weight gains in g. were: control without supplement 1483, minerals 1416, Aurofac-2A 1701, Fortafeed 1600, Aurofac-2A plus Fortafeed 1734, minerals plus Aurofac-2A 1667, minerals plus Fortafeed 1600, minerals plus Aurofac-2A plus Fortafeed 1667. Thus minerals reduced weight gain, but Fortafeed and still more Aurofac-2A increased it, and the best results were got when both Fortafeed and Aurofac-2A were given. The effects on feed efficiency were similar. All groups remained healthy. Neither Aurofac-2A nor Fortafeed affected the quality of the meat. Geese given minerals had livers on the average 49 g., nearly 40 per cent., heavier and the extra cost of the minerals, 1·67 schilling per bird, might be economically worth while if the livers were to be sold separately (here they went with the bird).—W. M. Deans.

COATES, M. E., DAVIES, M. K., HARRISON, G. F., KON, S. K. and PORTER, J. W. G. **The mode of action of antibiotics in chick nutrition. 2. The effect of penicillin in clean and stale premises.**

COATES, M. E. and PORTER, J. W. G. **3. The nature of the "infection" counteracted by penicillin.** *J. Sci. Food Agric.*, 1955, **6**, 419–421; 422–425. [Nat. Inst. Res. Dairying, Univ. Reading.]

For previous work by the authors in support of the theory that antibiotics exert their beneficial effect on growth by counteracting a transmissible "infection" see Abst. 1422, Vol. 22.

2. Chickens from an "infected" room used for intensive rearing where growth was sub-optimum were transferred to new premises and the "infected" house was thoroughly cleaned and fumigated. When day-old chickens were re-introduced, growth rate was better and the addition of penicillin to the diet gave only a slight response, 2·5 per cent. at 2 weeks. When further batches of chickens were introduced growth rate deteriorated and the effect of penicillin increased to 22 per cent. at 40 weeks, in spite of the use of disinfectants. In the new premises with "infected" chickens, growth was significantly depressed and penicillin was clearly beneficial.

Three experiments were made with chickens reared in field units. In the first, penicillin significantly stimulated growth in units deliberately "infected", but had no significant effect on "uninfected" chickens. In the 2 subsequent experiments in which the "uninfected" chickens were moved to fresh ground but the "infected" were not, the trend of effect was similar to that in the disinfected chick room, in that a small but significant response to penicillin occurred in the "uninfected" groups.

3. Preliminary results with chickens in isolation units, which are described, indicate that the "infection" could be transmitted by feeding the gut contents of "infected" chickens to newly hatched "uninfected" chickens. The infective agent was destroyed by autoclaving the gut contents. It was not present in the gut contents of uninfected chickens. It is suggested that the infective agent is a living organism or group of organisms.

SCHARPENSEEL, H. W. Über einige neue Probiotika und Antibiotika in der Geflügelernährung. **[New probiotics and antibiotics in poultry feeding.]** *Arch. Geflügelk.*, 1955, **19**, 380–384. [Dept. Agric. Chem., Araneta Inst. Agric., Manila.]

In view of the possible risks of using powerful antibiotics to rear animals for food production, it is suggested that more attention should be given to the substances with mild antibiotic activity which occur naturally in flowering plants, and which Winter (*Medizinische*, 1955, No. 2, 73) calls "probiotics". Some preliminary results are given of experiments with day-old chicks and pullets given young nasturtium leaves or an oily extract of these; from the third week until laying began they made better weight gains than a similar group given Aurofac. Results at least equal to those with Aurofac were also obtained with press juice from the leaves of *Cassia sophora*, and with small amounts of papain, a tenth or less of that theoretically required to digest the protein of the ration, and costing only 9 Pf. per bird for the 5-month growing period. All 3 supplements, particularly nasturtium, gave some protection against fowl-pox virus. Further experiments to test this, and on the use of the supplements for hens in lay, will be reported later. (See also Abst. 1256).

EBBELL, H. Der Einfluss von 3-Nitro 4-Hydroxy Phenylarsinsäure allein und in Kombination

mit einem Terramycin-Produkt auf das Kükenwachstum. [**Effect of 3-nitro-4-hydroxyphenylarsonic acid alone and in combination with a terramycin product on growth of chicks.**] *Arch. Geflügelk.*, 1955, **19**, 255–267. [Ovomaltine Farm, Oberwangen bei Berne.] English summary.

In experiments lasting 6 or 10 weeks with practical chick and broiler all-mash rations, neither 3-nitro-4-hydroxyphenylarsonic acid alone, at 50 g. per 1000 kg., nor terramycin at 0·04 per cent., nor both improved feed efficiency. Each gave better final weights than the basal rations alone, and both together improved final weights by from 17 to 27 per cent.—D. Duncan.

1301

ALMQUIST, H. J. and MERRITT, J. B. **The effects of a detergent in the diet of range turkeys.** *Poultry Sci.*, 1955, **34**, 740–741. [Grange Co., Modesto, Calif.]

The addition of 0·10 per cent. sodium alkylamyl sulphonate to the mash of range turkeys had little effect on rate of growth but improved feed conversion efficiency, particularly in hens. The hens consumed much more grain than the toms.

J. S. Thomson.

1302

FOX, T. W. **Effects of progesterone on growth and sexual development in S.C. White Leghorns.** *Poultry Sci.*, 1955, **34**, 598–602. [Massachusetts Agric. Exp. Stat., Amherst.]

Intramuscular injection of 2, 4, 8 or 16 mg. progesterone weekly for 12 weeks had no effect on average bodyweight gain or shank length of Single Comb White Leghorn chickens although there was greater variation in the treated groups. Comb index (height × length) and testis size were reduced by the treatment. Females removed from treatment after 16 weeks took longer to reach sexual maturity than controls.—J. S. Thomson.

EGG PRODUCTION

1303

GERRIETS, E., WERNER, C. and STAHL, H. Vergleichende bioklimatische Untersuchungen am Huhn unter verschiedenen Haltungsbedingungen. [**Comparative bioclimatic studies on hens under different housing conditions.**] *Arch. Geflügelk.*, 1955, **19**, 276–300. [Abt. Geflügelkrank., Humboldt Univ., Berlin.] English summary.

A long discussion, with references, on the effects of climate and housing on the health and performance of livestock, with special reference to poultry, occupies the first third of this paper. Thereafter the results of a one-year trial from October 1953 to September 1954 with 4 specially built henhouses at Damsdorf, Brandenburg are reported. The houses were (1) solidly built of 12-cm. brick, (2) lightly built of Heraklith slabs, (3) lightly built of double pine planking with Piatherm insulating material between, (4) lightly built of single pine planking with the front open. In other details they were similar. Full descriptions and photographs are given. All measured 2 × 2 × 2 metres and had 2 alternative sandy runs. Each housed 10 pullets and 1 cock of the Leghorn breed. In the morning and evening each group had 500 g. sprouted oats, at midday 1000 g. of a soft mash of steamed potatoes 1, green feed (in winter carrots) 1 and laying meal 3 parts. The percentage composition of the laying meal was : ground barley 66, protein concentrate (45 per cent. of animal origin) 10, ground oats 10, wheat bran 10, minerals and trace elements 3, charcoal 1. Laying meal was available in self-feeders at all times. Each group also had daily 2 ml. liver oil with additional vitamins A, D_2 and E. Records of temperature, humidity, feed consumption, weight gains and egg production are tabulated.

The total feed consumption in kg. was, for group 1, oats 198, mash 362, laying meal 60 ; the corresponding figures for the other groups were 196, 360, 59 ; 199, 358, 61 ; 196, 370, 62. In February, the coldest month, all the groups ate less oats and more mash, presumably because the mash was given hot. Consumption of both rose when laying began in March but fell to the usual amounts in April. The fowls in the open-fronted house did not eat more than the others even in very cold weather. When winter cold first set in in December the first 3 groups lost weight but not the group in the open-fronted house. Weight gains during the year were 404·5, 223, 337 and 332 g., respectively. Egg production in all groups fell in December. The monthly averages from October to February were 13·0, 15·1, 14·5, 13·6. Over the whole period the monthly averages were 16·8, 18·8, 18·3, 17·6 and the total egg weights 117, 123, 125, 118 kg. All groups remained healthy in spite of respiratory diseases in the neighbourhood. Slight frost damage to head appendages occurred in January and February, most severe in the open-fronted house, but combs were not permanently damaged. Freezing of eggs was avoided by collecting them at 2-hr. intervals. Further trials are being made.—W. M. Deans.

ATKINSON, R. L., FERGUSON, T. M., QUISENBERRY, J. H. and COUCH, J. R. **Dehydrated alfalfa meal, condensed fish solubles, distillers dried solubles and dried whey as supplements to an**

all-vegetable protein turkey laying diet. *Poultry Sci.*, 1955, **34**, 730–735. [Dept. Poultry Husb., Texas Agric. and Mech. Coll. System, College Station.]

Turkey hens were given a basal ration of soya bean meal, yellow maize, milo, minerals, vitamins and antibiotics. To this was added, at the expense of soya bean meal and milo, dehydrated alfalfa meal, alone or in combination with condensed fish solubles, dried whey, dried whey and condensed fish solubles, dried distiller's solubles, dried distiller's solubles and condensed fish solubles, or condensed fish solubles, dried distiller's solubles and dried whey. For 17 weeks hatchability and fertility were recorded in 2 periods, 1 to 11 and 12 to 17 weeks. The tocopherol content of the yolk in the 17th week was estimated.

The supplements did not improve fertility or hatchability in the first period; during the second period hatchability on the basal ration fell from 83·7 to 31·0 per cent., but in the groups getting supplements it was maintained at 54·3 to 81·0 per cent., the highest level being in the group getting dried alfalfa meal and condensed fish solubles. The tocopherol content of the yolks was higher than values reported in the literature, and was increased by the supplements. In the second period embryonic mortality during the first 7 days was reduced by dried alfalfa meal and during the last 4 days by the other supplements.—T. D. Bell.

1305

MAYFIELD, H. L., ODLAND, L. M., PAGE, L. and HALBROOK, E. R. **Egg quality as influenced by certain feed combinations.** *Montana Agric. Exp. Stat. Tech. Bull.* No. 493, November 1953, pp. 22.

Experiments were made over 5 years to compare mash mixtures containing 2 of the common grains, wheat, oats and barley, with a more complex mixture containing maize and milling by-products in their effects on egg size and quality. Some of the rations were supplemented with riboflavin, fish solubles or animal-protein factor.

Yolk colour of eggs from hens receiving maize was generally darker than from those not receiving maize, and palatability was better. Eggs from hens receiving 2 of the common grains were higher in vitamin B_1 than those from hens getting maize. A supplement of 2 mg. riboflavin per lb. feed increased the riboflavin content of the eggs from 2·41 to 3·97 μg. per g. The addition of condensed fish solubles to the ration containing wheat and oats affected egg quality measurements, but it had no effect when added to the ration containing maize, wheat and oats.

Except for egg weight and yolk colour all measurements of egg quality were similar for rations with and without animal-protein factor.

HARRAR, J. G. **Food for the future.** *Science*, 1955, **122**, 313–316. [Rockefeller Found., New York.]

A paper read at the symposium of the American Association for Advancement of Science in Berkeley, Calif., in December 1954.

1307

DICKINS, D. **The home-produced food supply of non-owner farm families. Some factors associated with it.** *Mississippi Agric. Exp. Stat. Bull.* No. 512, March 1954, pp. 24.

A survey was made in May and June 1952 of the value of home-produced food for the previous year in 443 white and negro non-owner farm families in the cotton areas of Mississippi and causes associated with differences in these values. Only families of 2 or more members were included. The average net income was $1389. There were 249 families using less than $75 per person per family of home-produced food and 194 families using over $75. The greatest differences were in the amount of animal products, especially milk, produced and used and in the amount of processed home-produced foods. Average total expenditure on food was $496 for the group producing less (44 per cent. of the net income) and $518 in the group producing more (30 per cent. of the net income).

BREIREM, K. Matforsyningen og jordbruksproduksjonen. [**Food supply and agricultural production.**] *Tidsskr. norske Landbruk*, 1955, **62**, 183–234.

This article reviews the major problems of world food production as set out chiefly in publications of The Economic Commission for Europe, FAO and FAO staff; of the growth of world population as discussed by Bennett (Abst. 4015, Vol. 24) and others, and finally discusses Norwegian diet. Supplies per head of the Norwegian population are about 3100 Cal. daily with 53 g. animal protein, chiefly from milk and fish. The shortages are of fruit and vegetables. A high proportion of the nation's food, reckoned in calories, is imported, but, in spite of the growth of population, the gross import of cereals and oilcakes has not risen since

the war because the use of concentrates for animal feeding has fallen. Agricultural technique has greatly improved. Yet Norway produces only 12 per cent. of the wheat it uses for bread and although milk production has risen slightly since 1950, it has not kept pace with demand. More wheat could be supplied by Sweden with advantage to both countries, and Norway requires a new and consistent policy in respect of subsidies on concentrates to encourage the improvement and greater use of homegrown feedingstuffs.—I. Leitch.

1309

NÖU, J. and NILSSON, O. Produktivitet och produktivitetsberäkningar inom jordbruket. [**Productivity and the estimation of productivity in agriculture.**] *Kungl. Lantbruksakad. Tidskr.*, 1955, **94**, 159–209. English summary.

As measures of production sales and turnover are rejected and the concepts of gross, " rensad " (gross less bought-in seed and feedingstuffs), and net production are discussed. The expression of production by number, weight or volume in terms of calories, crop units, or cereal units is reviewed and assessment in terms of money units, income or standard prices is considered, and later related to input in terms of labour units and land units. Efficiency and capacity to produce are then considered as criteria of successful production, the several concepts are linked and examples are given of their practical application to farming in Sweden.

JONES, W. D. and HALLETT, G. **An economic survey of beef production in Wales 1949-54.** *Univ. Coll. Wales, Aberystwyth, Dept. Agric. Econ.*, 1955, pp. 26.

The world meat situation is reviewed. Although world production of meat has increased since 1939, the amount exported and available to the United Kingdom is less than it was then. This underlines the necessity for an increase in home-produced beef.

To investigate the economics of fattening beef cattle in Wales a study was made from 1949 to 1954 of 31 farms in each of the first 3 years, 30 in the fourth and 23 in the last. The farms were from 72 to 600, average 300 acres, of which 2/3 was permanent grass. The number of cattle handled ranged from under 20 to over 250, with an average from 82 to 189 per farm. Most animals were of beef breeds, but there were some dual purpose, and some dairy, and most were steers. Fattening was the main enterprise on some farms, and on others it was combined with or subsidiary to dairying. There was no winter fattening in yards, but only summer fattening off grass. Just under half the stores were purchased in the autumn and kept in store condition until spring. The rest were bought in the spring. Costs of purchasing, keeping and fattening the animals and the income from their sale were recorded, showing the return per animal. This ranged from £12 16s. 10d. to a loss of 12s. 11d., average profit £6 7s. 2d. Comparison of the 5 worst and the 5 best showed that the difference in profit was not related to the size of the farm, the number of cattle handled or the cost of production. When spring and autumn purchases were compared, the higher price paid in the spring was offset by the cost of keeping through the winter. It was difference in weight between purchase and sale, and thus in rate of gain, that was related to the profit per animal. Thus skill in selecting stores and in management were of great importance.

Profits from beef production in Wales, though above those in 1949, are still not high, but the demand for beef is great, and its production is encouraged by deficiency payments and subsidies on hill cattle and calves. With improved grassland to increase output of beef per acre, improved dairy stock to reduce the acreage required for milk production, the use of dual purpose breeds which can be fattened when not required for dairy replacements, and a good supply of stores from upland farms not suited to fattening, but needing cattle in combination with sheep for pasture management, the beef industry can be maintained and improved with advantages to both producer and consumer.—T. D. Bell.

1311

PHILLIPS, J. R. E. **Economic studies in Welsh dairy farming. 5. General report on the costs of milk production for 60 herds during 1951-52. With summary tables for a reduced sample for 1952-53 and 1953-54.** *Univ. Coll. Wales, Aberystwyth, Dept. Agric. Econ.*, 1955, p. 42.

The conditions influencing costs and returns on Welsh dairy farms are discussed. It is shown that feedingstuffs and labour accounted for 57 and 17 per cent., respectively, of the gross costs. Food costs rose from £49 7s. in 1948–49 to £63 8s. in 1951–52. The average yield per cow rose from 666 to 703 gal. over the same interval. There was a wide variation in costs and returns between farms due to differences in size and geographical location of the farms, to differences in average yield per cow in the herd and to different methods of feeding and management. Tables summarising the costs and returns of a reduced sample of herds for 1952–53 and 1953–54 are given in an appendix.

1312

ROWBOTTOM, J. D. and HORSBURGH, A. S. **Report on costs of milk production for the year ended 30th September 1954.** *Edinburgh and East of*

Scotland Coll. Agric. Dept. Econ., Bull. No. 48, March 1955, pp. 32.

This report is based on the production records of 45 herds. All counties in the East of Scotland College area were represented. Compared with the previous year the average milk yield per cow increased by 10 gal. to 788 gal. The increase was largely due to increased summer milk production. The total net cost of keeping a cow for the full year was £90 5s. 2d. Cost of feedingstuffs formed 61 per cent. and cost of labour 19 per cent. of the total cost. A study of the feedingstuffs used on the different farms showed that grass silage was becoming increasingly popular.

The feeding of up to 1½ tons of concentrates per head per annum was shown to be profitable in herds giving an average yield of 1000 gal. per cow ; it would be uneconomic in herds where the average yield was only 750 gal. per cow.—J. N. Aitken.

1314

IMPERIAL CHEMICAL INDUSTRIES, LTD. **Milk from leys in the weald of Sussex. A case study of a small dairy farm.** *Agric. Development Dept. Bull.* No. 6, May 1955, pp. 42.

This bulletin describes the alterations in cropping and livestock production which have taken place on a small 95-acre, poor-land dairy farm during the years 1948 to 1953. The growing of cash crops was gradually abandoned, and the total acreage under tillage crops reduced. The most significant change in the cropping programme was the replacement of permanent grassland by leys. This, with a well planned programme of manuring, silage-making, haymaking and strip grazing, has enabled the farmer to increase the number of stock, reduce the amounts of purchased concentrates and obtain a bigger margin of profit per cow and per gal. milk.—J. N. Aitken.

1315

BEYNON, V. H. and DAVIES, T. H. **Production and profit on a small Devon farm.** *Agriculture, J. Minist. Agric. Engl.*, 1955, **62,** 258–262. [Dept. Econ., Univ. Bristol.]

An account is given of the management of a farm of 53 acres. By selecting replacements to the dairy herd from high-yielding heifers milk production has been increased. High production per acre has been achieved by concentrating on growing kale and well fertilised 3- and 4-year leys which are strip-grazed. The good utilisation of the land has allowed the dairy herd to be increased, and an attempt is made to keep the number of followers down to a minimum. The poultry section of the farm has also been increased. The improved management has increased the farm income threefold.—T. D. Bell.

1317

KOORNNEEF, H. De mogelijkheden van besparingen bij de voedering in de Nederlandse veehouderij. [**The possibility of economies in feeding in Dutch animal husbandry.**] *Landbouwk. Tijdschr.*, 1955, **67,** 403–419.

When the feed eaten by farm stock in the Netherlands is valued at market price a year's consumption totals 2·5 to 3 milliard gulden. A survey of the distribution of feed over the several classes of stock, with special reference to cattle (76), pigs (12) and poultry (6), which between them take 94 per cent. of the total feed in terms of protein and 92 per cent. in terms of starch equivalent, has been made with the help of agricultural organisations and a random survey of feeding practice, to cover 15 years' records, and the gross consumption is compared with feeding standards. The main assumption is that the stock population is unaltered in number and production over the period of survey ; losses in getting and preserving pasture products are ignored. There are known to be differences in the application of standards. In some districts cows, in milk and dry, are given 15 to 25 per cent. more than the standard allowance of starch equivalent (S.E.) ; heifers and calves get less than the standard. Further complications are that, in spite of similar chemical analyses, hay from clay soil is considered better than hay from sandy soil and that better than hay from peat soil.

In terms of S.E. pigs get 45 per cent. of their feed from mixed rations, 30 per cent. from home-grown grain, 20 per cent. from potatoes and some sugar beet, and 5 per cent. from whey and skimmed milk. In general allowances exceed the standards by about 11 per cent. in protein and 38 per cent. in S.E. Comparing different breeding centres feed per kg. weight increase ranges from 3 to 3·75 feed units and in general practice it is assessed at about 4.

Records of feed consumption by poultry are difficult of analysis, but in general consumption appeared to be about 6 per cent. above theoretical requirements.

Altogether it appears that the possible saving, in terms of imported concentrates, would be of the order of 175 million kg., valued at 40 to 50 million gulden annually. And that means a saving on total feed cost of about 2 per cent. Greater economies could possibly be made by improving the composition of rations and by replacing existing stock by more productive animals.—I. Leitch.

1318

BONADONNA, T. Riflessioni sulla produzione e sui consumi nazionali di prodotti di origine animale. [**Production and national consumption of products of animal origin.**] *Zootec. Vet.*, 1955, **10,** 216–218. [Ist. Sper. Ital. "L. Spallanzani" Fecond. Artific., Milan.]

Animal production is subsidiary, though complementary, to crop production in Italy, and animal products should not be exported at the expense of other products such as fruit, wine and rice. There is a great potential demand for the animal products at home. The majority, particularly in the south and the islands, are poorly fed, and too much is spent on luxuries. By educating the public and increasing their purchasing power, the potential demand should be made a reality, and the increased supply of animal products available from improved technique and from economically necessary imports would be absorbed.

1319

CONSOLINI, A. Della carne nelle zone tradizionalmente a produzione lattiera. [**Beef production in districts traditionally devoted to milk production.**] *Zootec. Vet.*, 1955, **10,** 196–204.

In Italy periodic crises arise in the milk market because of overproduction, and on the other hand production of meat is below requirements. It is suggested that dairy farms could even out the discrepancy by devoting more milk to rearing calves and then fattening them for slaughter. This would withdraw some milk from the market and at the same time increase the supplies of meat. For this dual purpose breeds are preferable. It is shown that at current prices such a programme would not reduce the farmer's profits.

HALNAN, E. T., MOSKOVITS, I. and THRELKELD, T. (Eds.) **Problems of animal feeding in Europe. Efforts towards self-sufficiency.** *FAO Agricultural Development Paper* No. 51 and *European Association for Animal Production Publ.* No. 3. Rome, Italy, June 1955, pp. viii+147.

Livestock feeding in Europe was the subject of a technical meeting convened jointly by FAO and the European Association for Animal Production in Paris from 23 to 28 March 1953. Fifty-seven delegates attended from 16 countries in Europe and North Africa and observers were sent by 3 other international organisations.

This publication has 5 chapters which deal comprehensively with the problems; they are based on papers prepared by 5 authorities and incorporate the discussions to which the papers gave rise. Professor A. M. Frens, Hoorn, discussed recent trends in the production and utilisation of feedingstuffs in Europe, dealing with the changes which have occurred in 10 of the countries of Europe in particular and proceeding to review recent developments in the production of feedingstuffs as grassland and green fodders or as arable crops and in the use of compound mixtures. Professor Crasemann, Zürich, dealt with technical problems arising from the more extensive use of homegrown feeds, the conditions influencing the amount of fodder consumed, the extent to which their protein contents limit the use of homegrown feedingstuffs, the adequacy of supplies of fat and the limitations of self-sufficiency on the farm either natural, from soil or climatic conditions, or artificial, from man's misuse of the soil and its products.

The 3 following chapters are on special problems of feeding livestock. Those of cattle feeding by Professor Breirem, Oslo, concern the principles of the evaluation of feeds, those of pig feeding by Professor Richter, Brunswick-Völkenrode, the use of homegrown feeds, minerals, vitamins and antibiotics, and those of poultry keeping by Dr. Halnan, Cambridge, the problems of bulk and fibre and of animal protein and antibiotics in the diet of poultry.

At the end of the meeting recommendations were approved on the drawing up of a general programme to assist individual governments in their long-term projects and on the need for standardising methods of calculating feed requirements and the value of available feedingstuffs. It was agreed also that EAAP should examine methods of calculating protein requirements, that work on the value of feeds should be attempted, and that FAO should continue its study of legislation governing the manufacture of and trade in compound feedingstuffs in European countries.

LETARD, E., LABOUCHE, C. and MAINGUY, P. Les sous-produits industriels dans l'alimentation animale. [**Industrial by-products in animal feeding.**] *Rev. Élevage Méd. vét. Pays trop.*, 1955, **8,** 285–296. [École Nat. Vét. d'Alfort.]

Industrial by-products for animal feeding are in small supply or non-existent in French West

Africa because the corresponding industries have not yet been developed. Such as there are, are used to a small extent for pig feeding in the ports. In 1953, 125,000 tons of groundnut cake were exported. Most of the article consists of descriptions and data on the composition of by-products from groundnut, oil palm, coconut, sesame, cotton, karité (a native tree), beref (*Citrullus vulgaris*), coffee and fish. Most of these are quoted from the literature, but local values are given for groundnut straw, sesame cake, beref cake and fishmeals.—W. M. Deans.

1322

JONES, W. D. **Economic factors in egg production.** *Univ. Coll. Wales, Aberystwyth, Dept. Agric. Econ.*, 1955, pp. 21.

To compete with Danish eggs on the free market it is necessary that the United Kingdom reduce the cost of production. This can best be done by using as much homegrown feed as possible, and high egg yields per bird are necessary. A survey was made of 6 flocks kept in batteries, 10 on deep litter and 4 on free range. The cost of feed was highest in batteries and lowest on free range, but under the intensive systems the birds could be kept under closer observation, with lower mortality rates, and with regular culling, only the high-yielding birds were maintained. This meant that profits per bird were higher. The production of eggs for the market when prices were highest was an added advantage. Capital outlay was highest for batteries, and for this reason deep litter would possibly be preferred for new enterprises, though accurate culling would not be so easy.

When deciding the time for hatching, or buying day-old chicks, the seasonal fluctuations of egg prices should be kept in mind. The price of culls and the value of the reduced number of eggs in the second year should be considered when the question of keeping hens for the second laying year arises. It might be better to keep culls until Christmas, when they would sell for more, but this would depend on the cost of their keep and the small returns from their eggs. Hatching or purchase of day-old chicks in autumn instead of spring is discussed.—T. D. Bell.

GÓMEZ, J. A. Algunos problemas de tenencia y uso de la tierra en Colombia. [**Some problems of tenure and use of land in Colombia.**] *Acta agronom., Colombia*, 1955, **5**, 67–115. English summary.

A description of conditions in Colombia shows the very low standard of living of the population, particularly in rural areas. Ignorance, a bad educational system, undernutrition resulting in illness, inability to work and a very short expectation of life which means that agricultural skill is not developed, all aggravate the state of affairs, and the distribution of the land plays a large part in creating and perpetuating the present conditions. A brief historical review shows how this system of land tenure has developed, in which a large proportion of the land is in the hands of a few owners, and is producing as little as one-sixth of what it could produce and supporting only a few of the people that it could support. Legislation introduced to improve things has been ineffective. In contrast to these vast enterprises there are some small holdings, but on them there are too many working, so that none can work to capacity. Here ignorance and poverty contribute to poor use of the land.

The solution does not lie in simple redistribution of the land. Industry should first be developed, so that it will be able to absorb the excess labour which will result from mechanisation and improved farming methods.—T. D. Bell.

DIET IN ETIOLOGY OF DISEASE

GENERAL

1325

ZORNIG, H. H. Untersuchungen zum Problem der Nutzungsdauer von Rindern des Verbandes "Rotbunte Schleswig-Holsteiner". [**The useful life of cows of the Red Pied Schleswig-Holstein Association.**] *Züchtungskunde*, 1955, **27**, 71–87. [Tierzucht Inst., Univ. Kiel.]

From the herdbook of the Red Pied Schleswig-Holstein Association were selected only those cows for which records were complete, in number 5376, about 7 per cent. of all entries between 1920 and 1952.

The cows which calved first at 2 years 7 months of age had the longest useful life of 6 years 7 months and 6·1 calvings. The useful life fell after a first calving at 3 years 5 months to 5 years 3 months, and there was one calf fewer. The cows which calved first at 2 years 7 months gave in all 84 kg. less milk annually than those which calved at 2 years 9 months. The best age for first calving was considered to be about 2 years 7 months to 2 years 10

months. Of all the cows 26·05 per cent. calved at this age, 15·87 per cent. earlier and 58·12 per cent. later.

The mean time between calvings was less than 1 year for 38·5 per cent. of the cows, more than 430 days in only 5·8 per cent. The commonest interval was 370 days. The reason given most often for loss of cows was sterility, 31·5 per cent., and the next was " sent for fattening ", 11 per cent., which also included sterile cows. With the third group, udder disorders, 8·28 per cent., these accounted for nearly half the losses. " Old age " accounted for 6·32 per cent., but included some cows only 8 years old. The percentage of cows discarded for sterility or sent for fattening was highest in the group with milk yields of 2500 kg. or less and fell with increasing yield. Half of those discarded for sterility or sent for fattening were within 2 years of their highest annual yield. The percentage discarded for udder disorders was lowest with low milk yields and rose with yield, but again nearly 60 per cent. were within 2 years of their peak output. The mean highest annual yield was given by cows 8 years old, with range from 5·5 to 10·5. The mean age reached by cows was 9 years 4 months, their useful life 6½ years and number of calves 5·8. As a result of selection, useful life increased with annual yield up to 5000 or 5500 kg.

The findings are discussed and compared with others in the literature.—D. Duncan.

1326

WITHERS, F. W. **Wastage and disease incidence in dairy herds.** *Vet. Rec.*, 1955, **67**, 605–612. [Minist. Agric. Vet. Lab., Weybridge.]

Records of 58 dairy herds in Surrey and 64 in Berkshire in 1950 to 1951 and of 55 in Surrey, 58 in Berkshire and 50 in Wiltshire in 1951 to 1952 were studied. Of these, 75 in the first year and 110 in the second were tuberculin-tested herds, the remainder being accredited or unregistered. It was understood that the farmers who co-operated in the investigation had the better managed farms, and the results would be slightly biased. The average herd sizes were 25, 31 and 33 for Surrey, Berkshire and Wiltshire, respectively.

Deaths and disposals were divided into 6 classes, the first 5 representing cows disposed of outside the dairy industry, because of natural death, age, infertility, poor yield or disease and accident, and the sixth representing disposals in the normal course of business, *e.g.*, sales within the industry. The average wastage for the 2 years represented by cattle in classes 1 to 5 was 19·1 per cent. of the total cows in the study, and by cattle in class 6 was 5·2 per cent. Of the deaths, 1·4 per cent. of all cows, 37 per cent. were associated with calving, 13 per cent. were due to bloat and 10 per cent. to accident and injury; the remaining 40 per cent. were due to miscellaneous causes such as yew poisoning, anthrax and blackleg. The animals culled for infertility, poor yield and age were grouped together since the distinction between these reasons for culling was not always clear-cut, the main reason given depending to some extent on the judgement of the farmer or recorder. These animals represented 11 per cent. of the total cows. It was found that of all pregnancies 1 in 14 ended in stillbirth or abortion, and it was thought that since the introduction of S19 vaccine abortions had been reduced: of the abortions recorded few were due to brucella. The incidence of retained placenta, milk fever and mastitis increased with age. Mastitis was generally found at the beginning of lactation, usually during the first few weeks, after which it decreased but occurred again towards the end. As a rule only one quarter was affected. The incidence was greater in the larger herds.

WHITEHAIR, C. K. and GALLUP, W. D. **A study of winter disorders in cows and ewes fed low-quality roughage.** *Oklahoma Agric. Exp. Stat. Tech. Bull.* No. T. 53, March 1955, pp. 31.

A high incidence of loss by death in range cows in Oklahoma was caused by a disorder typified by inability of the cow to get to her feet, lack of appetite and rough hair coat. It occurred almost exclusively in cows in late pregnancy, 4 to 7 years old, in late winter and early spring. The affected cows had been fed on poor hay or pasture, and the cause was thought to be underfeeding, particularly in respect of protein, though a few responded to Co treatment, and sometimes calcium gluconate and dextrose were effective. Improving the ration could bring cows back to health and prevent the occurrence of the disorders.

An experiment with pregnant ewes was made in which they were fed on poor hay typical of that used on farms where the disorder had occurred. Giving this hay alone resulted in signs similar to those in cows. Supplements supplying energy, in the form of maize starch, maize or molasses, protein as soya bean meal, maize gluten meal, solvent- or hydraulic-extracted cottonseed meal, and added Ca, P and trace minerals were tested for their ability to prevent the disorder. Urea nitrogen was also used to replace part of the protein supplement.

When no supplement was given many of the ewes died during pregnancy, and a small supplement of protein, though it prevented death, did not enable the ewes to produce vigorous lambs, and few of the offspring survived to weaning. Supplements supplying energy were not effective. Larger supplements of protein raised reproduction and lactation performance to normal, and there

was no advantage from adding minerals. In the deficient ewes anaemia developed to a greater degree during pregnancy and early lactation than in the ewes which performed normally. Levels of Ca, P and vitamin A in the blood did not suggest that deficiency of any of them was responsible in any way for the disorder. Urea was used satisfactorily to replace some of the protein, and the quality of the protein seemed to be immaterial.

RYDELL, R. O. **A new approach to bovine bloat therapy.** *J. Amer. Vet. Med. Assoc.*, 1955, **127,** 74. [Wheaton, Minn.]

Administration of calcium intravenously to cows suffering from parturient paresis was found to cause belching. It is suggested that in such cases the nervous mechanism associated with belching is less sensitive. Four bloated cows were treated by injection of calcium and success is claimed.—A. T. Phillipson.

1329

FERGUSON, W. S. and TERRY, R. A. **Bloat investigations.** *J. Agric. Sci.*, 1955, **46,** 257–266. [Imperial Chemical Industries, Ltd., Jealott's Hill Res. Stat., Bracknell, Berks.]

This is an account of many attempts to produce bloat. The administration of 2·5 litres of lucerne juice produced bloat fairly regularly; this is equivalent to about 5 kg. fresh lucerne. No method of preventing the bloat so produced was found except by using foam-breaking agents; these appeared to have some preventive action.

A. T. Phillipson.

BETTS, A. O., WHITTLESTONE, P., BEVERIDGE, W. I. B., TAYLOR, J. H. and CAMPBELL, R. C. **Virus pneumonia in pigs. Further investigations on the effect of the disease upon the growth-rate and efficiency of food utilisation.** *Vet. Rec.*, 1955, **67,** 661–665. [Dept. Animal Pathol., Univ. Cambridge.]

Five experiments at the Department of Animal Pathology, Cambridge University, and 3 at the Agricultural Research Council Field Station at Compton are reported. In each experiment littermate pairs of pigs free from virus pneumonia were used, one pig being retained as a control and one having injected into the lumen of the trachea suspensions of lung infected with virus pneumonia. In all, 120 pigs of several different breeds and breed crosses were used and environmental conditions varied considerably between experiments. The results from all experiments were similar. The control pigs showed no sign of infection with virus pneumonia either during life or at post mortem, but the infected pigs all coughed during life and at post-mortem examination most showed lesions of virus pneumonia. Occasionally, and usually between 19 and 26 weeks of age, infected pigs lost weight, their appetites became poor and rectal temperatures rose to above 104·5° F. The term "secondary breakdown" was used to describe this condition. At Cambridge, over all 5 experiments, infection with virus pneumonia caused an average depression in rate of growth of 16·7 per cent. and an average increase in meal eaten per lb. liveweight gain of 20·6 per cent. At Compton, over 3 experiments, the average depressions in growth rate and efficiency of food conversion caused by the infection were 17·1 per cent. and 24·6 per cent., respectively. The applicability of these results to field conditions is discussed.—I. A. M. Lucas.

1331

VESSELINOVITCH, S. D. **Electrophoretic studies of oedema disease in swine.** *Brit. Vet. J.*, 1955, **111,** 398–403. [Ontario Vet. Coll., Guelph.]

The pattern of the serum protein fractions of pigs in good health and pigs suffering from oedema disease was studied by electrophoresis on filter paper. The pigs were 2 and 3 months old. The pattern of the "normal" pigs was characterised by low γ-globulin, and the albumin : globulin ratio was 0·86. In infected pigs with clinical oedema there was a decrease of albumin and an increase of α- and γ-globulins, with an albumin : globulin ratio of 0·35. Infected pigs without clinical signs had low albumin but an increase in γ-globulin only, and the albumin : globulin ratio was 0·59. The changes in protein fractions were not specific enough to indicate the site of the disturbance which gave rise to them. It was thought that they might be a manifestation of reaction to stress.

WRIGHT, M. M. and TEMPERTON, H. **Curled tongue in turkey poults.** *Vet. Rec.*, 1955, **67,** 510–513. [Nat. Inst. Poultry Husb., Newport, Shropshire.]

Curled tongue in young turkeys was first noted at the above Institute in 1954 when the incidence was 16·4 per cent. in the first 6 hatches. The turkeys had been reared on a home-compounded dry mash. Subsequent hatches were used to investigate the cause. No genetic or nutritional cause was found, but the physical state of the ration was incriminated. Dry rations containing over 70 per cent. by weight of particles less than 1 mm. were liable to produce curled tongue. There was a high rate of recovery when the diet was changed from dry to wet mash.—J. S. Thomson.

DEFICIENCY DISEASES

1334

BRION, A. and PAGOT, J. Les carences alimentaires du bétail dans leurs rapports avec la pathologie animale. [**Feed deficiencies in livestock in relation to animal pathology.**] *Rev. Élevage Méd. vét. Pays trop.*, 1955, **8**, 223–276. [École. Nat. Vét., Lyons.]

The physiological role of minerals and vitamins and the signs of deficiencies in animals are described. Even when signs are not apparent, some deficiency is frequently there, and animals are in a precarious state of health, prone to infectious disease and parasitic infestation. This is true of most of French West Africa. As things are the nomadic life of most stock keepers is probably advantageous in that it avoids worse deficiencies by not overstocking the poor forage and soil.—T. D. Bell.

1335

ANDREWS, E. D. and ANDERSON, J. P. **The effect of cobalt topdressing in preventing cobalt deficiency disease of lambs in Southland.** *N.Z. Vet. J.*, 1955, **3**, 78–79. [Wallaceville Animal Res. Stat., Dept. Agric., Wellington.]

Lambs kept for 3 months on pastures topdressed with cobalt sulphate at 6 oz. per acre and then transferred to Co-deficient pasture were protected against deficiency for at least 17 weeks. It is concluded from this and other experiments that, in Southland, topdressing pastures with 5 oz. cobalt sulphate per acre in November should protect lambs against deficiency for at least 7 months.—D. Duncan.

1336

THAIN, R. I. **Cobalt deficiency in sheep and cattle. (With special reference to the Wynyard Veterinary district.)** *Tasmanian J. Agric.*, 1955, **26**, 154–164.

In 1952 unthriftiness in lambs in a flock at Seabrook in Tasmania was put down to Co deficiency and was successfully treated with Co. In the same year a tentative diagnosis of Co deficiency was made in another flock at Rulla. On this property a paddock on basaltic soil with an admixture of grey sand was bisected and half was dressed with cobalt sulphate at about 1 lb. per acre. Newly weaned lambs were run on both parts for 3 months, during which time those on the part dressed with Co gained on the average 48 lb. and the others 15 lb. One lamb in the untreated group died and one had to be treated with Co, and the rest had harsh wool, lacked energy and had dull and "rheumy" eyes. The part treated with Co was eaten bare while the untreated part contained plenty of grass, showing the effect of Co on appetite.

On another farm on red-brown basaltic soil, fortnightly drenching of lambs with cobalt sulphate caused them to gain in 5 months 33·4 lb. more than untreated controls. Six control lambs out of 19 died, but no treated lamb.

The incidence of Co deficiency and of possible Cu deficiencies in cattle in the Wynyard district is discussed.—D. Duncan.

1337

KEENER, H. A., PERCIVAL, G. P. and MORROW, K. S. **Cobalt deficiency in New Hampshire cattle, sheep, and goats.** *New Hampshire Agric. Exp. Stat. Bull.* No. 411, June 1954, pp. 14.

Cobalt deficiency in sheep, goats and cattle was widespread in New Hampshire until 1944, but since then it has been almost eliminated by including 2 g. Co sulphate in each ton of concentrates. Abundant growth of forage caused by heavy manuring with artificial fertilisers or poultry manure appeared to give hay with a low Co content. In experiments with yearling lambs, although those given a diet deficient in Co did not show extreme signs of Co deficiency, their weight gains were less than half those of animals given a supplement of Co. Experiments with young Holstein calves showed that they could tolerate 100 times the amount of Co usually supplied as a supplement. Co was more effective in preventing or curing a deficiency when given by mouth than by vein. Co was thought to play an important part in rumen function.—T. D. Bell.

SUTHERLAND, A. K., MOULE, G. R. and HARVEY, J. M. **On the toxicity of copper aminoacetate injection and copper sulphate drench for sheep.** *Austral. Vet. J.*, 1955, **31**, 141–145. [Dept. Agric. Stock, Brisbane.]

Further trials were made to test the toxicity of copper glycinate (aminoacetate) injected and of copper sulphate as a drench to correct copper deficiency in sheep (see Abst. 2668, Vol. 24).

In the first experiment 2 ewes injected with 40 mg. Cu as copper glycinate and 4 with 60 mg. showed no toxic sign except for local lesions. One ewe injected with 80 mg. Cu died within 48 hr. and one showed anorexia, abdominal pain and progressive weakness; 2 others showed no sign except for local lesions.

In a second experiment copper glycinate was injected at the rate of from 5 to 60 mg. Cu into 7 groups of wethers and copper sulphate (3·5 per cent. solution) was given as a drench, from 1 to 2 fluid oz., to other 3 groups. Three of the wethers injected with 60 mg. Cu died; 2 died after drenching with 2 oz. copper sulphate solution and 2 were missing, presumed dead. A drench of 1½ oz. produced persistent diarrhoea.

PANTIĆ, V. and JOVANOVIĆ, M. Enzootska struma domaćih žibotinja. 2. Histološka ispitivanja. [**Enzoötic goitre of domestic animals. 2. Histological study.**] *Acta vet., Belgrade*, 1955, **5**, No. 1, 13–32. [Inst. Histol. Embryol., Vet. Fac., Belgrade.] English summary.

For part 1 see Abst. 3998, Vol. 24. [The original is in Serbian, not Russian.]

When thyroids of domestic animals from the goitre area were examined histologically, the commonest type of enlargement was diffuse colloid goitre, especially in sheep and cattle but also in horses and goats. Diffuse parenchymatous goitre was found also in goats and horses, and the larger size of the colloid goitre in these species was ascribed to its having developed from the parenchymatous form. Early pathological changes were found in glands of normal size. Adenoma was occasionally found in horses, sheep and goats. Toxic goitre (*Struma basedowificata*) was found in several horses and a cow.—D. Duncan.

1341

BARBER, R. S., BRAUDE, R. and MITCHELL, K. G. **Studies on anaemia in pigs. 2. Comparison of haemoglobin levels in blood of pigs reared indoors and outdoors on pasture.** *Vet. Rec.*, 1955, **67**, 543–545; 546. [Nat. Inst. Res. Dairying, Univ. Reading.]

For part 1 see Abst. 5970, Vol. 25.

Hb values of pigs reared indoors and outdoors from birth to weaning were studied. The pigs reared indoors were given daily doses of 2 ml. Fe pyrophosphate from the 4th to the 11th day, supplying 30 mg. Fe. The outdoor pigs were moved outside at 4 days of age to fold units, with grass runs which were renewed daily; they received no Fe supplement. From 14 days old both sets of pigs had access to creep feed, and the amount eaten was recorded. Liveweights were also recorded weekly. The trial took place during the summer.

Hb values in the indoor pigs rose from 9·27 g. per 100 ml. blood on the 4th to 11·26 g. on the 14th day, and then fell rapidly to 8·5 g., at which level they remained fairly constant, showing only a slight rise by the 8th week. The average liveweight at weaning was 32·3 lb. Consumption of creep feed increased from 0·2 to 5·9 lb. weekly.

In the outdoor pigs Hb values fell from 10 to 8·5 g. from the 4th to 7th days, then rose steadily for 3 weeks to a level of 12 g., where they remained. Liveweight at weaning was 39·6 lb., and consumption of creep feed rose to 9·5 lb. weekly during the last week. The growth rate of the 2 groups was the same up to the 3rd week, and it was only then that the outdoor group began to outstrip the indoor. The period of more rapid growth coincided with the higher Hb values of the outdoor pigs. It was thought that intake of Fe by the indoor pigs was too low, since very little was supplied by the creep feed or the milk consumed; in the outdoor pigs sufficient was probably obtained from the grass and earth. Further investigations with pigs raised indoors are in progress to find the effect of more frequent doses and of higher Fe intake from increased consumption of creep feed.—T. D. Bell.

1342

MCDONALD, F. F., DUNLOP, D. and BATES, C. M. **An effective treatment for anaemia of piglets.** *Brit. Vet. J.*, 1955, **111**, 403–407. [Benger Res. Labs., Holmes Chapel, Cheshire.]

A report is given of successful experiments in the treatment of piglet anaemia with an iron-dextran preparation given intramuscularly.

In 8 young anaemic pigs Hb was raised from 5·1 to 9·8 g. per 100 ml. within a fortnight after the first injection. The Fe in this preparation was almost completely absorbed. A comparison was made with injected Fe phosphate, which was poorly absorbed. A first injection of iron-dextran should be given after the first week of life, with a second 2 weeks later, or it is suggested that a single injection of 20 mg. Fe per lb. could be given at about 10 days to tide the young pig over the critical stage.—J. S. Thomson.

DISEASES OF METABOLISM

1343

SJOLLEMA, B., GRASHUIS, J., VAN KOETSVELD, E. E. and LEHR, J. J. Onderzoekingen over kopziekte. [**Grass tetany.**] *Tijdschr. Diergeneesk.*, 1955, **80**, 579–604. [Inst. Moderne Veevoeding "De Schothorst", Hoogland.] English, French and German summaries.

An experiment is described with 8 milk cows, procured on the basis that they had already had one or more attacks of grass tetany. They were

in full lactation. Their daily ration was of 8 kg. bought-in hay, 25 kg. fodder beet and concentrates, according to milk yield, 6 to 7 kg. Four of the cows were given, while still stall-fed, a mixture of potassium acetate and dipotassium phosphate, equivalent with that in the ration to a total of about 550 g. K daily. Two of these and 2 without extra K were pastured on a lush, heavily manured grazing, the other 4 on a less rich pasture. One of those given K had an attack while still in stall. The other 3 and one of those not given extra K and on the less rich pasture had attacks soon after grazing began. One of the cows receiving extra K had a serum Mg value of 1·6 to 1·7 per cent. on pasture and 1·3 per cent. during the attack. It was therefore atypical. The others at the time of the attack had serum Mg values from 0·1 to 0·3 per cent.—I. Leitch.

1344

HEAD, M. J. and ROOK, J. A. F. **Hypomagnesaemia in dairy cattle and its possible relationship to ruminal ammonia production.** *Nature*, 1955, **176,** 262–263. [Chem. Dept., Nat. Inst. Res. Dairying, Univ. Reading.]

When cattle are turned out to spring grass the ammonia content of the rumen fluids rises. Cattle feeding on hay and concentrates were given 1250 g. ammonium carbonate or ammonium acetate into the rumen, and ruminal ammonia contents comparable with those found on spring grass were produced after 4 days. Urinary excretion and blood levels of magnesium were reduced. Though the level of blood Mg was not reduced as much as has been found in hypomagnesaemia on spring grass, it was thought that the results of the test indicated that increase of ammonia in the rumen was responsible for impaired absorption of Mg.

POISONS OCCURRING IN FOOD

1345

WALKER, G. W. and MILNE, A. H. **Fluorosis in cattle in the Northern Province of Tanganyika.** *E. African Agric. J.*, 1955, **21,** 2–5. [Vet. Res. Lab., Mpwapwa.]

Preliminary results are reported of a survey of the incidence of fluorosis in cattle, first noted in 1952, in 3 areas near Mount Meru strewn with volcanic ash. Water from many of the streams rising in the mountain showed high F contents, up to 45·5 p.p.m. Cattle from farms in the 3 areas were examined and lesions of the teeth were apparent in nearly all, the severity depending on the F content of the drinking water. Exostoses were apparent on the ribs in 10 per cent. of the animals in the highly affected area and bone ash showed an F content of about 0·6 per cent. The survey is being continued.—J. S. Thomson.

1346

HALE, W. H. and KING, R. P. **Possible mechanism of urea toxicity in ruminants.** *Proc. Soc. Exp. Biol. Med.*, 1955, **89,** 112–114. [Iowa Agric. Exp. Stat., Iowa State Coll., Ames.]

In an experiment with 13 lambs, 7 to 12 months old, ammonium carbamate was given by intravenous or subcutaneous injection, or introduced into the rumen by drench or into the abomasum by injection. Urea and ammonium chloride were also given intravenously.

Ammonium carbamate given intravenously in doses of 2, 3, 4, 5 or 6 g. caused increasing signs of toxicity, the largest resulting in death. The signs of toxicity were similar to those reported in poisoning by urea. Twenty g. injected into the abomasum, and 25 g. by drench into the rumen, also caused death. When injected into the abomasum just after feeding, 25 g. caused severe signs and 15 g. mild signs, but the lambs recovered. Subcutaneous injection of 7 g. had no ill effect.

Intravenous injection of 2 g. ammonium chloride caused dizziness and lethargy, which were not the same as the signs of toxicity usually seen, and from which the lamb recovered. Intravenous injection of 5 g. urea had no toxic effect.

In no case was any appreciable rise in the level of ammonia in the blood observed. It is suggested, in the light of these results, that urea toxicity in the ruminant may be due to ammonium carbamate, not to ammonia.—T. D. Bell.

1347

HVIDSTEN, H. **Studies on the effect of nitrite in pig feed.** *Acta Agric. scand.*, 1955, **5,** 245–256. [Div. Animal Nutrit., Agric. Coll. Norway, Vollebekk.]

A method of preserving herring meal with sodium nitrite has been developed and the proposed standard has been set at an upper limit of 0·2 part nitrite per thousand. The effect of this meal and of meals containing higher amounts of nitrite was tested with pigs.

The feeding of about 200 g. daily of a meal containing 10 times the above amount of nitrite had no effect on growth, feed efficiency, pork quality or health of the pigs, and no methaemoglobin was found in the blood. When up to 260 g. of a meal containing 4 parts nitrite per thousand were given methaemoglobin appeared in the blood, but there was no apparent effect on growth. At this level of nitrite, blood methaemoglobin was higher when an equivalent amount of nitrite was given as an aqueous solution of $NaNO_2$. At the highest level of nitrite intake, and with cod liver oil in the diet, the deposition of vitamin A in the liver was inhibited.—J. S. Thomson.

1348

PAYNE, W. J. A. and NAIDU, R. K. **The toxicity of creeping indigo ("Indigofera endacaphylla".)** *Fiji Agric. J.*, 1955, **26,** 1–3. [Dept. Agric. Serv., Dept. Agric., Fiji.]

Indigofera endacaphylla [*? endecaphylla*] (creeping indigo) is a useful pasture legume palatable to cattle and goats. In view of its alleged poisonous properties an experiment was made with 5-week-old chickens in which creeping indigo was incorporated in rations at levels of 5 and 10 per cent. The results were inconclusive in that no death was reported at the 10 per cent. level, but 3 out of 16 died at the 5 per cent. level. Rate of growth was adversely affected at the high level.

1354

SOUTHCOTT, W. H. **Observations on the removal of *Oesophagostomum columbianum* Curtice from sheep grazing on green oats and on pastures.** *Austral. J. Agric. Res.*, 1955, **6,** 456–465. [Div. Animal Health and Prod., C.S.I.R.O., Reg. Pastoral Lab., Armidale, N.S.W.]

When 6-month-old wethers were infested with larvae of *Oesophagostomum columbianum*, Curtice, grazing on green oats reduced the number of eggs in the faeces. There was no reduction when similar animals grazed on native pasture. After 3 months' grazing, 24 adult worms per sheep remained in those on green oats and 108 in those on native pasture. On green oats, the faeces were softer and had an acid reaction, but on native pasture they were alkaline. Liveweight gains were not significantly different, since the animals on native pasture were given an adequate supplement of lucerne hay. In wethers free from adult worms before grazing, green oats delayed the development of the larvae 8 weeks, and after 3 months' grazing those on native pasture had 91 adult worms, those on green oats only 20.

A similar comparison was made with grazing on green oats, phalaris-subterranean clover pasture, red clover and native pasture. Again there was a reduction in faecal egg counts on green oats but not on native pasture. There was also a reduction on the other pastures, but not as rapid as on green oats. After 3 months' grazing the number of adult worms remaining was 23 on green oats, 57 on phalaris-subterranean clover, 51 on red clover and 77 on native pasture. Faeces became softer on all crops except native pasture, but only green oats reduced the *p*H.—T. D. Bell.

1355

RIEDEL, B. B. **Leucine and fowl ascarids.** *Poultry Sci.*, 1955, **34,** 587–589. [Dept. Animal Dis., Mississippi Exp. Stat., State College.]

Day-old New Hampshire chickens were given a ration low in leucine, or the same with a supplement of DL-leucine. After receiving the ration for 2 weeks some of the chickens on each level of leucine were infected with *Ascaridia galli*, and the others were kept as controls. The birds were examined *post mortem* 3 weeks after being infected. According to the number of worms found in the chickens, and the length of the worms, the level of leucine did not appear to have any effect on resistance to ascarid infection. The higher level of leucine gave better growth than the low, and the birds appeared healthier. Growth in the infected groups

compared favourably with growth in the control groups at the corresponding level of leucine.

MARKHAM, F. S., PRICE, R. J., SEEGER, K. and WHITE-STEVENS, R. **Dietary aureomycin chlortetracycline and immune response to Newcastle disease and infectious bronchitis.** *Poultry Sci.*, 1955, **34**, 554–559. [Lederle Labs. Div., American Cyanamid Co., Pearl River, N.Y.]

In 3 field trials involving 35,000 chickens, the effect on resistance to disease of giving up to 300 g. chlortetracycline per ton feed from hatching was investigated. Some birds were vaccinated against Newcastle disease and infectious bronchitis viruses. Serological data and exposure of the birds to virulent Newcastle disease virus showed that administration of the antibiotic at any level up to 300 g. per ton of feed did not affect response to the vaccines and subsequent resistance to the infections. The results are discussed in relation to contrary findings by other workers.—T. D. Bell.

7. BOOK REVIEWS

1357

KOLMER, J. A., SPAULDING, E. H. and ROBINSON, H. W. **Approved laboratory technic.** Appleton-Century-Crofts, Inc., New York, 1951, 5th ed., pp. xii + 1180. Price 90s. net.

This is a textbook of medical laboratory techniques and will be of interest mainly to clinical laboratory workers. The practical details of the techniques which are considered are so full, however, that biochemists who only occasionally require to employ them should be able to do so with a minimum of difficulty. The book is also instructional in that the principles underlying the experimental procedures are discussed at some length. There are 7 sections, which deal with (1) general laboratory methods, including microscopy and the care, inoculation and bleeding of laboratory animals, (2) clinical pathological methods, including the examination of tissue fluids, blood, excretions and secretions, (3) bacteriological, mycological and virological methods, (4) parasitological methods, (5) serological methods, (6) chemical methods and (7) pathological methods. The arrangement of material does not seem ideal in that the techniques which might be required for application to a single specimen, *e.g.*, blood or urine, may be distributed over several sections, widely separated in the book. The chapters dealing with chemical methods occupy less than 200 of the 1150 pages of the book and only about 100 pages are given to blood and urine, the remainder being concerned with fundamental techniques such as weighing, preparation of volumetric solutions and the use of colorimeters and with methods for toxicological examination of specimens. In general only one method is described for each estimation and no assessment is made of the relative merits of other methods in use.

H. G. Bray.

1358

GLICK, D. (Ed.), **Methods of biochemical analysis. Volume 1.** Interscience Publishers, Inc., New York and London, 1954, pp. x+521. Price 75s.

Each of the articles in this volume consists of an account of the background to the topic under consideration and a critical discussion of previous work, followed by experimental details of procedure recommended by the authors. The subjects considered are: estimation of sulphydryl groups in certain biological substances, analysis of phenolic compounds of interest in metabolism, microbiological assay of antibiotics, microbiological estimation of vitamin B_{12}, chemical estimation of ascorbic, dehydroascorbic and diketogulonic acids, zone electrophoresis, chromatographic separation of steroids of the adrenal gland, analysis of radioactive iodine compounds from the thyroid gland and body fluids, chemical estimation of choline, estimation of nucleic acids, estimation of raffinose and kestose in plant products, estimation of adenosine triphosphate (firefly luminescence and other methods), assay of catalases and peroxidases, estimation of hyaluronidase *in vitro*, ultracentrifugal analysis of serum lipoproteins, assay of urinary neutral 17-ketosteroids. The standard of this first volume of the series is high and the production excellent. It will undoubtedly be of interest and practical value to biochemists in many fields of investigation.—H. G. Bray.

1359

ALBRITTON, E. C. (Ed.) **Standard values in blood. Being the first fascicle of a handbook of biological data.** W. B. Saunders Co., Philadelphia and London, 1953, pp. x + 199. Price 31s. 6d.

In this compilation from the literature, the first instalment of the Handbook of Biological Data, the systems of preparation and presentation of the data are those which were later used for the second instalment, *Standard Values in Nutrition and Metabolism*, to which reference has already been made (Abst. 3153, Vol. 25). Over 600 investigators took part in the assembly of the information and in reviewing it. The result is 101 tables on

the composition and reactions of blood which cover 143 demy quarto pages and for which the bibliography runs to 46 more pages. Where possible code letters are added to show by which of 4 methods the upper and lower limits of the 95 per cent. ranges have been inferred. The whole is a serviceable manual for those interested in the wide subject of the composition of blood.—D. Harvey.

1360

WEINMANN, J. P. and SICHER, H. **Bone and bones. Fundamentals of bone biology.** Henry Kimpton, London, 1955, 2nd ed., pp. 508. Price 100s.

The first edition of this book was published in 1947, and the reviewer regrets not having seen it. The introduction begins thus : " Although created and constantly molded by man, language and linguistic terms influence man's thinking to an astonishing degree. All too often, linguistic ambiguities are the cause of unnecessary confusion." The authors have avoided such confusion. Nearly every section of the book begins with clear definitions of the terms used, and this practice, combined with clarity and conciseness of the literary style and the good format, produces a book which is a joy to read, apart from turns of phrase which are perhaps better American than English. Here is proof that even a difficult subject—and there is no doubt of the complexity of bone biology—can be presented in a way which makes the reader feel at home with it. How often, after struggling to decipher in other works pages which the authors have sought to cover with the longest imaginable words twisted into the longest possible sentences, does the same reader feel that here is a subject beyond his comprehension?

The authors are a pathologist and an anatomist, and the book is intended as " a challenge to the research worker ; a guide to those who work on bone and on bones in their medical speciality : orthopedists, radiologist, metabolists, dentists, orthodontists ; and an aid to the teacher who wants to integrate his particular field into the greater unit of biology ". It should serve all these purposes. The section on normal structure and growth of bone and bones occupies only 120 pages, but within this small space there is no lack of interest, and material also to stimulate controversy. For example, the authors intend " to bury once and for all the specters of ' halisteresis or decalcification ', ' interstitial growth of bone ', ' physical plasticity ' and ' creeping replacement ', which are resurrected again and again by the magic of the imagination ".

Most of the remainder of the book is devoted to pathology, but there are chapters on the influence of vitamins and on the effect of minerals on bone and bones. In the chapter on minerals there is an unfortunate lapse into that ambiguity so happily absent elsewhere. On page 297 we read : " Since calcium is so readily available, a deficiency should be expected only as a consequence of general malnutrition ; for example, in famine districts or among the underprivileged. It has been established that about one-half of the American dietaries are below the safety level in calcium intake. In most instances, the calcium deficiency is caused by a decrease in, or lack of, absorption." It must be supposed that the " availability " of calcium referred to in the first sentence is commercial and not physiological. America, after all, is a land flowing with milk and ice-cream. What evidence supports the second sentence, which appears directly contradicted by the third? The criterion of safety is surely the absence of deficiency.

The book is profusely illustrated, mostly with photomicrographs of unusual excellence and, thanks to the good quality of the paper, well reproduced ; there is a bibliography at the end. It is worth every penny of the high price, and one hopes that libraries can be persuaded of its value. The reader will need no persuasion.—D. Duncan.

1361

RURAL RECONSTRUCTION ASSOCIATION. **Feeding the fifty million. A report of the Rural Reconstruction Association Research Committee on the increase of agricultural production.** Hollis and Carter, London, 1955, pp. 138. Price 12s. 6d.

The fifty million to whose feeding the Research Committee of the Rural Reconstruction Association has, since its appointment in 1947, given its attention and towards whose welfare the recommendations in this book are directed are the inhabitants of the United Kingdom. At present they grow only about half of what they eat. Early in the report, in a short section dealing with home production, the Committee emphasises the long-term and risky nature of farming as an occupation. For the farmer the risks are personal ones and to him stability and fairness of prices are unconditional prerequisites.

Britain's agricultural resources and their present mode of utilisation are next considered under the three main headings of land, the human factor and capital. On this there follows under the same three headings and in what is the report's most important chapter, an examination of possible methods whereby the use of these resources might be improved. It is here, as the Committee well recognises, that highly controversial subjects are being dealt with such as land use, on which agricultural and industrial interests may clash, land value taxation, on which agriculturists and economists may be opposed, and soil fertility, on the maintenance of which disagreement exists among

agriculturists themselves. Many of the proposals will call for change not only at the agricultural but also at the national level. The further study which they will require may take a long time as, for example, will amendment of the law dealing with common land by the Royal Commission, the forth-coming appointment of which was announced at about the same time as this report was published.

In the last chapter possible changes in the pattern of consumption are suggested with special reference to wheat, oils and fats, meat, eggs and milk products. The increase in the consumption of liquid milk and the preference for lean meat and bacon have reduced home supplies of fat. The raw materials for margarine and cooking fat are now the weakest link in the chain of supplies.

But only slightly less in degree of importance is another supply problem, that of rural depopulation. Of every 10,000 workers in Britain there were, in 1952, only 353 in agriculture. For many of the 97·5 per cent. outside the industry and lost in our conurbations this report, were it to reach them, would provide interesting and salutary reading.

For a Progress Report published in 1951 see Abst. 2561, Vol. 21.—D. Harvey.

1362

SHERLOCK, S. **Diseases of the liver and biliary system.** Blackwell Scientific Publications, Oxford, 1955, pp. xv + 720. Price 50s.

The great increase in information on liver disease since the beginning of the second world war made clinicians aware of the need for an authoritative review of the present position and of modern literature. Dr. Sheila Sherlock has accomplished this task with outstanding success. With her colleagues at the Postgraduate Medical School, Dr. Sherlock has contributed greatly to the recent advances in knowledge of hepatic disease.

In this book diseases are classified according to the functional and morphological changes to which they give rise. Clinical and laboratory methods are described which are of value in identifying and in assessing the degree of damage to each of the four hepatic components: the liver cell, the vascular system, the reticulo-endothelial system and the bile ducts. In this way the pattern and trend of individual diseases can be more clearly presented. The author has the gift of lucidity and this book will be valued by both clinical and laboratory workers. It is beautifully produced.

SPECTOR, H., PETERSON, M. S. and FRIEDEMANN, T. E. (Eds.) **Methods for evaluation of nutritional adequacy and status. A symposium.** Quartermaster Food and Container Institute for the Armed Forces, Chicago 9, December 1954, pp. vii + 313.

In this report of a symposium held under the auspices of the U.S. Army the methods of evaluation of diets and the status of populations are dealt with authoritatively by two types of investigator, those in nutritional laboratories to whom the Army has referred the problems arising in connection with the feeding of the armed forces and those whose experience has been of nutrition either under field conditions in the campaign in Korea or under experimental conditions in physiological laboratories.

Rather more than half of the book is in four chapters, three dealing with the evaluation of protein, vitamin and mineral supplies. Much of the information in them is from animal experiments and the fourth chapter in this section deals specifically with the use of animals for this purpose. The remaining two chapters are on the significance for man of this knowledge, one giving an assessment of the methods of study of populations and the other reporting a round-table discussion on body composition.

Contributions on different aspects of the measurement of protein adequacy were given by H. H. Mitchell, P. R. Cannon, J. N. Williams and J. B. Allison. Discussions were initiated by O. A. Bessey on levels of vitamins in blood and by W. G. Unglaub and Grace A. Goldsmith on urinary excretion tests. Balance studies with macro-elements were discussed by D. M. Hegsted and the function of trace elements in blood formation by G. E. Cartwright, C. J. Gubler and M. M. Wintrobe. The principal contributors to the final discussion were M. I. Grossman, J. Brožek, D. E. Bass, W. R. Best and A. R. Behnke.

The background of the symposium may have been defence against war or its actual prosecution, but the peaceful applications of this summary of scientific knowledge on nutrition are obvious.

D. Harvey.

SMITH, R. W. (Jr.), GAEBLER, O. H. and LONG, C. N. H. (Eds.) **International symposium, October, 1954. The hypophyseal growth hormone, nature and actions.** Blakiston Division, McGraw-Hill Book Company, Inc., New York, Toronto, London, 1955, pp. xv + 576. Price 90s.

The symposium recorded in this volume, held at the Henry Ford Hospital in Detroit in 1954, was attended by 300 people. According to the editors of the report "the enigmatic pituitary growth hormone had been under study by one full generation of investigators and . . . present at the symposium were all the scientists, with few exceptions, who had been intimately concerned at one time or other with this most elusive of the pituitary hormones . . . it was a memorable experience to have witnessed the joint participation of such eminent investigators ".

In 5 parts there are 29 papers and the discussions which followed them. Beginning with a paper entitled " What is growth? " by Paul Weiss, the list includes such names as Alfred Wilhelmi, Hans Selye, Honor B. Fell, H. L. White, E. B. Astwood, S. J. Folley and Laurance W. Kinsell. The material included the preparation and properties of the hormone, its effects on specific tissues, its relation to nutrition and nitrogen metabolism, the production of diabetes and ketosis in experimental animals, a session on growth hormone and cellular systems, two papers on lactation and finally two on the disappointing results so far obtained in human subjects.

Clearly this symposium is one not to be disregarded by the research worker interested in the pituitary hormones. No wider usefulness can yet be claimed for it. To quote the editors again, the symposium " was held to sift over the rapidly accumulating data, to compare techniques of study, to attempt a resolution of disturbing differences, and to stimulate new approaches which some day may bring usefulness to this most intriguing pituitary substance ".

The book is clearly printed on good paper, and illustrated.—D. Duncan.

1368

INTERNATIONAL ASSOCIATION OF GERONTOLOGY, LONDON. **Old age in the modern world. Report of the third congress 1954.** E. & S. Livingstone, Ltd., Edinburgh, 1955, pp. vii + 647.

After the public oration by Miss Margery Fry and the presidential address by Dr. J. H. Sheldon on the Social Philosophy of Old Age, this report is divided into 17 chapters, not always identical with the sessions of the congress.

Chapter 4 deals with nutritional aspects of ageing and includes 5 papers: C. M. McCay, on bridging the gap between research and gerontological nutrition; H. M. Sinclair, on the dangers of overfeeding; E. M. Widdowson and R. A. McCance, on the response of well-nourished old men to starvation and of undernourished old men to unlimited food; W. Schulze, on protein metabolism and requirement in old age; N. W. Shock, D. M. Watkin and M. J. Yiengst, on metabolic aspects of ageing. Chapters 5, on tissue changes, 6, on cancer, and 12, on cardiovascular diseases, contain papers of nutritional interest, including one by W. S. Hartroft, on ageing of the cardiovascular system produced in young rats by choline deficiency, and a series of 4 papers on atherosclerosis by F. M. Antonini.—D. Duncan.

R., Waugh, R. K., Edwards, J. R. and Whisenhunt, M. R., simple and complex starters and hay for dairy calves; Hardison, W. A., Graf, G. C., Linkous, W. N. and Engel, R. W., Sudan grass silage for milking cows; Johnston, J. E., Naelapaa, H., Stone, E. J., Vizinat, J. J. and Frye, J. B. (Jr.), effect of nutrition and climate on summer milk production of cows; Seath, D. M., Lassiter, C. A. and Rust, J., hay supplement for milk cows on pasture; Lassiter, C. A., Denton, T. W., Brown, L. D. and Rust, J. W., pelleted calf feeds; Rusoff, L. L., Landagora, F. T. and Harris, B. (Jr.), streptomycin for dairy calves; Musgrave, S. D., Montgomery, R., Poitras, P. E., Kiern, O. and Ronning, M., low phosphorus and semen production of young dairy bulls; Lassiter, C. A., Taylor, J. A.; Davis, C. L. and Denton, T. W., chromogen and chromic oxide studies with dairy bullocks; Marshall, S. P. and Somers, H. L., temporary and permanent pastures for dairy heifers; Loewenstein, M., Cenco moisture tester for milk analysis; Whitaker, W. M., Van Horn, A. G., Lush, R. H. and Throop, B. T., effect of grazing on alfalfa-orchard pasture; Davis, C. L., Lassiter, C. A., Seath, D. M. and Rust, J. W., dicyandiamide and urea for dairy cattle; Leighton, R. E. and Rupel, I. W., milk-replacer formula for dairy calves; McCullough, M. E., winter pasture for dairy heifers; Thomason, E. L. (Jr.) and Ronning, M., grain feeding and milk production; Vizinat, J. J., Johnston, J. E. and Frye, J. B. (Jr.), effect of temperature and humidity on lactating cows; Underwood, L. M., Miller, W. J., Dalton, H. L. and Rogers, T. H., Tift Sudan and Starr Millet pastures for milking cows in summer; Driggers, J. C., fish body oils in chick rations; West, J. W., amino-acid and protein supplements for cottonseed meal in broiler rations; Huston, T. M., artificial light for turkeys; Naber, E. C. and Morgan, C. L., feather meal for poultry; Creech, B. G., Elam, J. F., Jacobs, R. L. and Couch, J. R., antibiotics in laying rations; Smith, R. M., range and confinement for laying pullets; Patrick, H., enzymes in poultry rations; Harris, A. J., Holmes, C. E. and Bywaters, J. H., granite grit for chicks; White-Stevens, R. H. and Jukes, T. H., antibiotics for chickens; Kent, O. B., restricted feeding of chickens; Guidry, B., controlled and full feeding of pullets; Watts, A. B., restricted and full feeding of chickens; Sullivan, T. W. and Stephenson, E. L., feather meal for broilers; Greene, D. E. and Stephenson, E. L., amino-acid supplements and protein level of broiler rations; Camp, A. A., Quisenberry, J. S. and Couch, J. R., vitamin A supplements for broilers; Patrick, H., Schweitzer, G. K. and Stow, G., vitamin D storage, response and digestion time in chicks and eggs measured using ^{45}Ca.

Proceedings of the 15th International Veterinary Congress, Stockholm, 1953. Part 1, 517–652.

There are 22 papers, on ruminants except where otherwise shown: Phillipson, A. T., digestion; Oyaert, W.

and Bouckaert, J. H., amino-acids in rumen ; Loussee, A., N metabolism ; Robertson, A. and Thin, C., ketosis ; Talsma, D., acetonaemia *post partum* ; Alström, I., P metabolism (rat) ; Jovanovic, M., P metabolism (rat) ; Field, H. I., Cu and growth ; Bouckaert, J. H. and Oyaert, W., Mg in blood ; Allcroft, R., Mg in blood ; Alvarez Betes, J., P deficiency ; Schofield, F. W., muscular dystrophy ; Ludvigsen, J., muscular degeneration (pig) ; Bolle, W., vitamins and protein in enzoötic heart failure (pig) ; Perry, F. A. and Gilman, J. P. W., riboflavin deficiency and reproduction (rat) ; Forenbacher, S., vitamin B_1 deficiency (horse) ; Saatçioglu, S., racecourse disease and vitamin C (horse) ; Sengir, E., tuberculosis and vitamin C (guineapig) ; Schoop, G., vitamin A deficiency and infection (young animals) ; Ender, F. and Helgebostad, A., yellow fat disease (fur animals) ; Hoflund, S., Holmberg, J. and Nihlén, H., fat necrosis ; Reinius, L., biosynthesis of linoleic acid (rat).

9. FOOD AND AGRICULTURE ORGANIZATION (AND OTHER ORGANIZATIONS) OF THE UNITED NATIONS

Monthly Bulletin of Agricultural Economics and Statistics. Vol. 4, No. 9, September 1955, pp. 44. Price $0.50. Vol. 4, No. 10, October 1955, pp. 62. Price $0.50. P. 1. The postwar recovery of agriculture. A summary of Part 1 of *The state of food and agriculture*, 1955. *Review of a decade and outlook.* See p. 1140, Vol. 25.

Vol. 4, No. 11, November 1955, pp. 48. Price $0.50.

Yearbook of Fishery Statistics. 1952–53, Vol. 4, Part 2. International trade. Rome, Italy, 1955, pp. xi + 328. Price $3.00.

1952–53, Vol. 4, Part 1 (1954 Supplement). Selected catch and landings statistics, 1938, 1947–54. Rome, Italy, 1955. Price $1.00.

Food Balance Sheets. Second Issue. Rome, Italy, 1955.

This second issue of food balance sheets refers to 33 countries and gives 83 balances of which 21 are for pre-war years. They can be regarded as final since none refers to a year later than 1952. The tables include the data under 17 headings and conclude with an assessment of the daily consumption of total protein, with the proportion from animal and vegetable sources, of total fat and of energy per head of population. For the first issue see p. 501, Vol. 19.

Grain Exports by Source and Destination, July 1954-June 1955. Rome, Italy, October 1955, pp. 33. Mimeographed. Price $0.25.

Commodity Policy Studies No. 8. The international effects of national grain policies. Rome, Italy, September 1955, pp. 20. Price $0.25.

Commodity Reports. Fats and Oils No. 6. Rome, Italy, October 1955, pp. 67. Price $0.25.

Agricultural Development Paper No. 51. Problems of animal feeding in Europe. Rome, Italy, June 1955, pp. 147. Price $1.50. (See Abst. 1320, Vol. 26).

Legislation and other measures in European countries on the manufacture of and trade in compound feeds. Rome, Italy, March 1955, pp. vii + 81. Price $1.50.

The laws which operate at present in 16 European countries for controlling the manufacture of and trade in compound feedingstuffs are cited and summarised. For most of the countries there is provided also an evaluation of the legislation.

Problems of food and agricultural expansion in the Far East. Rome, Italy, November 1955, pp. vii + 78. Price $0.75.

This publication is in 2 parts. The first is the Report of the FAO Regional Consultation on the Selective Expansion of Production and Consumption in the Far East. The meeting was held at Kandy in June 1955 and was attended by delegates from Burma, Ceylon, India, Japan, Pakistan, Philippines, Thailand and Viet-Nam. They described recent developments in agricultural practice in their countries and the change in consumption of wheat at the expense of rice which has occurred in the region was found to be of consequence to both exporting and importing countries. Expansion of consumption and of agricultural production within the territories and complementary developments within the region were discussed on the basis of the paper prepared for the Consultation by FAO and published with its 6 annexes as Part 2 of this publication. It reviews the trends of agricultural production and of food consumption, considers how the pattern of production is influenced by consumption and emphasises the need for integration in the approach to the problems of production.

Activities of FAO under the Expanded Technical Assistance Program 1954-55. Rome, Italy, 1955, pp. viii + 99. Price $1.00.

This report differs from earlier annual reports in format and in its being presented in relation to the Organization's five departments, Agriculture, Economics, Fisheries, Forestry and Nutrition. An introductory statement describes the effects which the continuance and, in some cases, the increase of their financial support, given by 61 countries at the Pledging Conference in November 1954, had on the FAO programme of work. In agricultural spheres examples of efforts in plant production, animal disease control, pasture management and dairying are cited. In those of nutrition, education and training schemes, joint undertakings with UNICEF in feeding children and the organisation of national nutrition and home economics services are described.

N.A. and R., January 1956

10. DEPARTMENTAL AND OTHER REPORTS

UNITED KINGDOM.

Rowett Research Institute, Bucksburn, Aberdeenshire, Scotland. Report for the academic year 1954-1955. Pp. 49.

Utilisation of protein and nitrogenous compounds by ruminants.
Nitrogen metabolism of rumen micro-organisms.
Nitrogenous constituents of leaves, peptides, etc.
Soluble carbohydrate of grass.
Polysaccharides of rumen bacteria : serological identification of rumen organisms.
Availability of copper in herbage.
Properties of ciliate protozoa of sheep's rumen.
Holotrich carbohydrate enzymes.
Fermentation of hemicelluloses by rumen bacteria.
Urease-positive rumen bacteria.
Saccharolytic bacteria of rumen.
Lipase (esterase) activity of rumen bacteria.
Metabolism of phospholipids in mammary gland.
Rumen bacterial fat.
Milk fat, blood lipids and muscular dystrophy.
Chromatography of fatty acids.
Absorption from the alimentary tract of sheep.
Metabolism of short-chain fatty acids by tissues of the sheep.
Calorimetry : gradient layer calorimeter.
Adrenal physiology of the sheep.
Microflora of the caeca of chickens.
Activity and control of the stomach of sheep : rumination : effect of acid solution in rumen.
Chemical study on diet change in sheep.
Protein metabolism : specific activity and time curves for normal, fractured and cortisone-treated rats after injection of a hydrolysate of ^{14}C-labelled protein.
Effect of nutrition on an outbreak of Tyzzev's disease in mice.
Anaemogenic action of dietary calcium carbonate (mouse).
Plane of nutrition and haematological findings (rat).
Protein, vitamin and energy requirements of pigs.
Proteins in poultry rations, evaluation.
Dietary energy and poultry nutrition.
Studies on skeleton and dentition of hill sheep.
Evaluation of roughage as source of energy for sheep.
Distribution of vitamin D in sheep.
Effect of level of mineral, energy and vitamin D intake on mineral reserves of sheep.
Effect of different planes of nutrition during first two years of life on growth, yield and health of cows.
Effect of high levels of vitamins and of penicillin in rations of pigs housed in warm and cold pens.
Interaction between planes of feeding and genetic type of pig.
Copper sulphate in rations for growing bacon pigs.
Efficiency of food conversion for mutton and milk in two crossbreeds of sheep.
Value of heather, according to age and season, to the grazing sheep.
Effect of constant daylight/darkness rhythm on wool production of sheep.
Radiological study of the skeleton and dentition of hill sheep.

NEW ZEALAND

Department of Agriculture. Annual Report of the Director-General of Agriculture for the Year ended 31 March 1955. Pp. 164.

Rickets-producing factor in green feed.
Effect of lowering the level of nutrition and starvation in sheep.
Effect of excess vitamin A on hogget thrift.
Growth of hoggets on white clover and perennial ryegrass.
Post-lambing nutrition of ewes.
Measurement of feed intake of grazing sheep.
Effect of plane of nutrition on lifetime production of sheep.
Non-protein nitrogen and amino-acid nitrogen in blood of beef cattle grazing pasture.
Uniformity trials with identical and fraternal twins.
Rearing calves on different planes of nutrition, lifetime project.
Short-rotation and perennial ryegrass for milk production.
Estimation of body fat of pasture-fed beef cattle from measurement *in vivo* of body water by means of antipyrine.
Cobalt deficiency in soils.
Goitrogenic action of kale.
Copper and molybdenum in pastures and soils.
Rumen chemistry of the lamb and of older sheep.
Rumen flora studies on sheep : variation in microbial end-products, rumen function in thrifty and unthrifty hoggets ; effect of level of feeding on microbial concentrations.
Chemical composition of ewe's milk.

THE COMMONWEALTH BUREAU OF ANIMAL NUTRITION

SUMMARY 300

REFERENCES 301

DURING the past twenty years a large amount of information about vitamins in foods has accumulated. The main object of most investigators has been to determine the average concentration in whole foods, but the literature contains also many references to the distribution of vitamins in particular tissues. Information on this question has not, perhaps, received as much attention as it deserves, in view of its practical importance in relation to the conservation of vitamins during the preparation and processing of food, and of its interest for plant and animal physiology.

An attempt has therefore been made to assemble the recorded facts in an accessible form, and to outline any general patterns of vitamin distribution in different kinds of food. Where possible, physiological factors responsible for the observed patterns of distribution, and practical applications of present knowledge, are discussed.

SCOPE OF SURVEY

The present review is based primarily on a survey of literature covering the period from the beginning of 1938 to the middle of 1954. Some of the most important earlier studies have been included also. Though the emphasis is on foods commonly used for human consumption in the United Kingdom, imported as well as locally grown materials have been included and most of the foods studied are widely used in other countries also. Unless otherwise stated, all information given refers to the fresh food, as produced on the farm, or as purchased.

Some aspects of vitamin distribution in the tissues of foods have previously been discussed by Fenton (1940), Cruickshank (1940–41), Simpson (1943), Holman (1945–46) and Blaxter and Brown (1952); in addition, Waisman and Elvehjem (1941) prepared a useful compilation of their own and other workers' values for the average concentrations of vitamins in animal tissues. No recent detailed survey of the literature appears to have been made.

The present review is concerned more with the relative differences between the concentrations of vitamins in tissues than with the concentrations themselves, but some of the recorded values have been assembled in tabular form. The values selected (see Tables 1 to 7) are in each case those of investigators who examined a variety of different tissues from a particular plant or animal product and who used methods of analysis based on well established principles. The values chosen illustrate the main trends in vitamin distribution, but it should be noted that they do not necessarily represent the best available figures for the *average* concentrations in the particular foods.

A wide variety of methods has been used for the examination of tissues, including qualitative histochemical techniques as well as biological and chemical methods of vitamin estimation. In many instances the same general conclusion has been reached by a number of investigators, providing some assurance that the methods used are suitable and the findings valid. Where, from the nature of the techniques used, it seemed possible that the results obtained might be misleading, attention has been drawn to the methods employed.

The term vitamin A, as used in the present review, refers to the pre-formed vitamin, the expression "vitamin A activity" being used where it was uncertain from the evidence supplied whether the particular food contained pro-vitamins A also. The expression "total carotenoids" is used where it was stated that the total pigment extractable by a fat solvent was estimated colorimetrically in terms of β-carotene, and "carotene" where it appeared that the fraction analysed approximated to β-carotene, or to utilisable or total carotene.

With vitamin C, though many of the methods used measured the total vitamin activity, it was ascorbic acid alone that was estimated in a number of instances. Since, however, most fresh plant materials contain very little dehydroascorbic acid, and since many workers provided evidence that no appreciable amount of the latter was present, the term "vitamin C" has been generally used, and the term "ascorbic acid" adopted only in a few instances where it appeared that ascorbic acid alone was estimated and where relatively little confirmatory information was available.

With vitamin E, the term "vitamin E activity" has been used when biological tests were made, and the term "tocopherols" when tocopherols present were estimated by chemical methods and the results were given for each tocopherol individually or for mixed or total tocopherols.

EVIDENCE CONCERNING FOODS OF PLANT ORIGIN

The information summarised about foods of plant origin deals chiefly with members of the vitamin B complex and with vitamins C and E, but some information is given also about the distribution of the pro-vitamins A (carotenoids), which are common constituents of plants. Vitamin A itself does not occur in plant tissues, and vitamin D does not appear to be present in living tissues of higher plants, although its presence has been detected in a number of sun-dried plant products.

Cereals

It has long been known from animal feeding tests on milling products that vitamin B_1 is distributed unevenly within cereal grains, being concentrated in the germ and bran. Some information about the distribution in cereals of other vitamins also has been obtained through the analysis of milling fractions.

In recent years special techniques have been developed for the examination of individual grains and much has been discovered about the exact sites of maximum vitamin concentration.

Vitamin B_1. Hinton (1942), working at the Cereals Research Station, St. Albans, first showed by dissection of wheat grains and analysis of the dissected fractions that vitamin B_1 is concentrated in the scutellum portion of the germ, a finding which was confirmed by Ward (1943) and by Jackson, Doherty and Malone (1943). It was estimated that the scutellum, although representing only a small proportion of the weight of the grain, contributed about 60 per cent. of the total vitamin B_1 (Jackson *et al.*, 1943; Hinton, 1944; van der Mijll Dekker, 1951). By further use of the dissection technique, Hinton (1947) showed that most of the remainder of the vitamin (32 per cent. of the total in the wheat grain) was present in the aleurone layer. In studies of other cereals, Hinton (1944) showed that the scutellum contributed 49, 82, 85, and 28 per cent. of the total vitamin B_1 in the hull-free kernels of barley, rye, maize, and oats, respectively.

Somers, Coolidge and Hamner (1945) used an entirely different technique for examining wheat grains, based on conversion of the vitamin B_1 present in a cut surface of the grain into thiochrome *in situ* by treatment with alkaline

ferricyanide, and measurement of the relative intensity of fluorescence in ultraviolet light of the different parts of the grain. They concluded that the vitamin B_1 in wheat is located chiefly in the aleurone layer, in the endosperm cells adjoining the aleurone cells at the base of the crease, in the scutellum, and in the endosperm adjoining the scutellum. Their findings were later confirmed by Pollock and Geddes (1951) using the same technique.

Holman and Godden (1947) analysed dissected fractions of oat grains and found that the hull of the ripe grain contained no measurable amount of vitamin B_1, and the central endosperm very little. Most of the vitamin B_1 was located in the bran and germ fractions, the former contributing slightly more of the total vitamin of the grain than the latter. It was estimated that the bran fraction contributed from 44 to 61, the scutellum from 25 to 27, and the whole germ from 36 to 42 per cent. of the total vitamin B_1 in the hull-free kernel.

Pulkki and Puutula (1947) examined grains of several cereals by analysing successive fractions removed by an emery scouring machine, as well as by dissection, and confirmed that most of the vitamin B_1 in wheat, barley and rye is located in or near the germ. They concluded that vitamin B_1 is more evenly distributed in the kernels of oats than in those of wheat and barley, that oat bran is rich in vitamin B_1, and that oat hulls contain only small amounts of the vitamin.

Detailed dissections made by Hinton (1948) on two samples of rice showed that the scutellum contributed from 44 to 50, the aleurone layer from 33 to 35, the embryo from 10 to 12 and the endosperm from 6 to 9 per cent. of the total vitamin B_1 of the grain. Simpson (1951), using the technique of Somers *et al.* (1945), found that the vitamin B_1 in rice was concentrated in the germ, particularly in the scutellum and adjacent cells of the endosperm.

Riboflavin. There is much evidence to show that the distribution of riboflavin in the wheat

TABLE 1

CONCENTRATION OF B VITAMINS IN AIR-DRY TISSUES OF MATURE CEREAL GRAINS

* Not stated whether outer or inner endosperm, presumably the latter.

grain is more uniform than that of vitamin B_1 (Hinton, 1942; Jackson *et al.*, 1943; Somers *et al.*, 1945). From examination of a cut surface of the grain in ultraviolet light Somers *et al.* (1945) concluded that the germ and aleurone layer were the regions of highest concentration, that there was a uniform distribution in different parts of the germ, and that the bran appeared to contain some riboflavin. Pollock and Geddes (1951) confirmed the conclusions of Somers *et al.* (1945) with respect to wheat, and Simpson (1951) concluded that in rice the maximum concentration of riboflavin was in the germ, the distribution within the germ being more uniform than that of vitamin B_1.

Nicotinic acid. There is considerable evidence that the nicotinic acid in the wheat kernel is located chiefly in the bran. Andrews, Boyd and Gortner (1942) reached that conclusion from a study of milling fractions of wheat, and Jackson *et al.* (1943) from analyses of millstreams and dissected fractions of the grain. More recently, Heathcote, Hinton and Shaw (1952) showed by dissection that the aleurone layer contributed 82 and the scutellum only 1·3 per cent. of the total nicotinic acid in two samples of wheat.

It has been demonstrated (see, *e.g.*, Chaudhuri and Kodicek, 1950) that wheat bran contains a precursor of nicotinic acid, which is readily converted to the free acid by hydrolysis with alkalis, but more slowly with acids. Heathcote *et al.* (1952) found no increase in their values when alkaline, instead of their usual method of acid, digestion was used, showing that their results must have included the nicotinic acid derived from this precursor, as well as that present as the acid and its amide.

With maize, the concentration of nicotinic acid is higher in whole grains of sugary varieties than in those of ordinary starchy varieties (Mather and Barton-Wright, 1946). The finding has been subsequently confirmed by a number of investigators and evidence has been produced that the nicotinic acid concentration is an endosperm character related to specific genes carried by the seed (see, *e.g.*, Richey and Dawson, 1951; Teas and Newton, 1951). Heathcote *et al.* (1952) examined by dissection grains of both these kinds of maize. Their results showed that in the aleurone layer and scutellum there was no appreciable difference in the concentration of nicotinic acid between the sugary and starchy varieties, but that in the endosperm the concentration was considerably higher in the sugary than in the starchy variety. In both, the aleurone layer was much richer in nicotinic acid than the scutellum or the endosperm and contributed from 59 to 63 per cent. of the total nicotinic acid in the whole grain.

Hinton and Shaw (1954) examined two varieties of rice and found that from 79 to 86 per cent. of the total nicotinic acid was in the pericarp and aleurone layer and from 12 to 18 per cent. in the endosperm. There was a notable decrease from the outer to the inner portion of the endosperm. The whole germ (embryo and scutellum) contributed only from 2 to 4 per cent. of the total nicotinic acid.

Vitamin C. The seeds of cereals, like those of many other species of plants, are devoid of vitamin C when in the mature, dry state (see *e.g.*, Daniel and Munsell, 1937).

Vitamin E. As early as 1925 Evans and Burr reported that vitamin E activity is low in the endosperm but high in the germ of wheat, maize and oats (Evans and Burr, 1925). More recently, Binnington and Andrews (1941) extracted the oil from each of the milling products of a hard and a durum wheat, and estimated tocopherol in the oil by a chemical method. They did not estimate the several tocopherols individually. It was concluded that in both wheats about 55 per cent. of the tocopherol was in the germ. In the hard wheat most of the remainder was in the endosperm adjacent to the bran, but in the durum wheat it was fairly evenly distributed throughout the endosperm.

General Conclusions

The available evidence shows that in mature cereal grains vitamin B_1 is concentrated in the scutellum portion of the germ and in the aleurone layer. In most cereals a higher proportion of the total vitamin B_1 of the grain is contributed by the scutellum than by the aleurone layer, but in oats the bran fraction, which includes the aleurone layer, supplies more than the scutellum. The endosperm contains very little vitamin B_1.

The germ and the aleurone layer appear to be the regions where the highest concentration of riboflavin occurs in the kernels of wheat and rice, but the distribution of riboflavin in the tissues is more even than that of vitamin B_1.

The nicotinic acid in the kernels of wheat, maize and rice is located chiefly in the aleurone layer; very little is contributed by the germ.

Vitamin E is concentrated in the germ of wheat, maize and oats.

Fruits

Apples and Pears

B vitamins. James (1944) found that the concentration of riboflavin in the peel and core of both apples and pears was higher than in the flesh, but that the flesh contributed the greater part of the total riboflavin of the fruit. In apples and pears, respectively, the flesh (cortex) contributed from

54 to 64 and 79, the peel from 20 to 27 and 15, and the core (including the calyx, placenta and seeds) from 16 to 19 and 6 per cent. of the total riboflavin.

Teply, Strong and Elvehjem (1942) reported that the concentration of nicotinic acid was much higher in apple and pear peelings than in the corresponding peeled fruits and Toepfer, Zook, Orr and Richardson (1951) that the concentration of folic acid in apple peelings greatly exceeded that in peeled fruit.

Vitamin C. Much evidence has accumulated to show that the concentration of vitamin C is higher in the skin or peel of the apple than in the cortex. The evidence relates to Bramley's Seedling and Newton Wonder apples (Bracewell, Kidd, West and Zilva, 1931), two United States varieties (Fellers, Isham and Smith, 1932), five English varieties (Birch, Harris and Ray, 1933), Bramley's Seedling (Olliver, 1936), Bramley's Seedling and Cox's Orange Pippin (Chappell, 1940), sixteen United States varieties (Eheart, 1941), New Zealand apples (Keys, 1943), 3 varieties of cider apples (Pollard, Kieser and Bryan, 1945; Kieser and Pollard, 1946), numerous varieties of English apples (Kieser and Pollard, 1947), and 24 Canadian varieties (Grant, 1947). Chappell (1940), however, found a lower concentration of ascorbic acid in the peel of market-purchased Worcester Pearmain apples than in the cortex. In the United States varieties the concentration was from 3 to 10 times higher in the peel than in the cortex (Eheart, 1941) and in New Zealand apples it was from 5 to 14 times higher in the skin than in the cortex (Keys, 1943). There is some evidence that the concentration is higher in the outer flesh than in the flesh near to the core (Bracewell *et al.*, 1931).

In the pear, also, it has been reported that the concentration of vitamin C is higher in the peel than in the cortex (Olliver, 1936; Chappell, 1940).

Citrus Fruits

Vitamin C. Many reports are available to show that the concentration of vitamin C is higher in the peel than in the juice of citrus fruits. The evidence relates to tangerines and Seville and sweet oranges (Bacharach, Cook and Smith, 1934), Seville oranges (Olliver, 1936), several species of citrus fruit grown in Japan (Fujita and Ebihara, 1939), Spanish and Jaffa oranges (Chappell, 1940), and South African oranges (Lampitt and Baker, 1942). Bacharach *et al.* (1934) found no difference in ascorbic acid concentration between the whole peel and juice of the lemon, but Deaker (1952) found a higher concentration in the peel than in the juice of New Zealand lemons of the Meyer and Standard types. The difference was less pronounced in the former than in the latter type.

Bacharach *et al.* (1934) showed that in both the orange and the lemon the concentration of ascorbic acid was much higher in the outer yellow skin of the peel (flavedo) than in the inner white skin (albedo), and that the pips of Seville oranges contained no measurable amount. In Seville oranges 40 per cent. of the total ascorbic acid was located in the flavedo, 45 per cent. in the albedo, and 15 per cent. in the juice.

It was reported by Chappell (1940) that when oranges were cut longitudinally into quarters and the quarters analysed separately, there were slight differences in ascorbic acid concentration of both peel and juice between one quarter and another. In one sample of Brazilian oranges but not in another Chappell found a slightly higher concentration in the juice than in the peel.

Lampitt and Baker (1942) found no difference in vitamin C concentration between the pulp and the juice of South African oranges.

Other Fruits

Carotene. Ellis and Hamner (1943) reported that the concentration was higher at the stem than at the blossom end of ripe tomato fruits.

B vitamins. The evidence of James (1944) showed that the concentration of riboflavin was higher in the peel and core of the tomato than in the flesh, but that the flesh contributed the greater part of the total riboflavin of the fruit. It was estimated by James that the flesh including the placenta contributed 65, the core, including the endocarp and seeds, 20, and the peel 15 per cent. of the total riboflavin. There is also some evidence that the concentration of nicotinic acid is higher in tomato peelings than in the peeled fruit (Teply *et al.*, 1942).

In the pineapple, Haagen-Smit, Strickland, Jeffreys and Kirchner (1946) found variations in vitamin B_1 concentration from one part of the interior of the fruit to another. A higher concentration was found at or near the core than near the shell, and a slightly higher concentration at the bottom than at the centre or top of the fruit.

Vitamin C. In the tomato Maclinn and Fellers (1938) reported that the concentration of vitamin C was highest in the seeds and gelatinous material of the locule, but that the outside flesh and skin contributed most of the total vitamin C of the fruit. Wokes and Organ (1943) found that the concentration in the seeds was much less than in the whole fruit and the concentration in the skin higher than in the flesh or juice. Le Riche and Burger (1946), who analysed the skin, flesh and pulp (all parts of the fruit except the seeds) separately, reported that in immature as well as in ripe tomatoes the skin had the highest concentration and the flesh the lowest.

In the ripe fruits of paprika (*Capsicum annuum*) examined by Beckley and Notley (1943) the concentration of ascorbic acid was higher in the pericarp than in the placentas, which in turn were much richer than the seeds. It was estimated that the pericarp contributed from 88 to 92, the placentas from 7 to 12, and the seeds from 0·3 to 0·4 per cent. of the total ascorbic acid of the fruit.

In several other species of fruit also it has been found that the concentration of vitamin C is higher in the outer than in the inner tissues. Thus, Olliver (1938) and Burkhart and Lineberry (1942) found that the concentration was higher in the cortex than in the medulla of the strawberry, and Kirk and Tressler (1941) and Schroder, Satterfield and Holmes (1943) that the concentration in the skin of the peach exceeded that in the flesh. According to Schroder *et al.* (1943) the concentration was higher in the outer flesh than next to the pit. In papayas (*Carica papaya*), Fujita and Ebihara (1939) found that the concentration was higher in the skin than in the flesh, and Robinson and Courtice (1940) that the concentration in the portion of the fruit just under the skin exceeded that in the inner portion.

In peeled bananas Thornton (1943) found a uniform distribution of vitamin C between different parts of individual fingers, different fingers, and different hands of the same lot, provided that all were at the same stage of ripeness. The concentration in all parts rose slightly in the early stages of yellowing, and then decreased steadily with advancing ripeness.

According to Haagen-Smit *et al.* (1946) the concentration of vitamin C is higher in the core of the pineapple than in the flesh near the core or near the shell, and higher at the bottom than at the centre or top of the fruit.

General Conclusions

In many fruits (*e.g.*, apples, pears, citrus fruits, papayas, peaches and tomatoes) the concentration of vitamin C is higher in the outer skin or peel than in the inner flesh or pulp. A similar relation may apply to riboflavin and to nicotinic acid, at

TABLE 2

CONCENTRATION OF VITAMIN C IN FRESH TISSUES OF FRUITS *

Fruit	Tissue or part of fruit	Vitamin C (mg. per 100 g.) Sample 1	Sample 2	Sample 3	Authority

any rate in the apple, pear and tomato. The proportion of the total vitamin C of the whole fruit which is present in the outer tissues has not always been determined, and may be small in thin-skinned fruits. In citrus fruits it is known to be considerable.

In apples, pears and tomatoes the concentration of riboflavin is higher in the core than in the flesh. The available evidence suggests that a similar relation may apply to vitamin C in tomatoes. Variations in vitamin C concentration within the flesh have been recorded in a number of species of fruits; in the apple, peach and papaya the concentration is higher in the outer than in the inner flesh. In oranges and paprika fruits the seeds contain little or no vitamin C.

Vegetables

Legumes

Vitamin C. The results of Olliver (1936) for green peas and of Lampitt, Baker and Parkinson (1943) for runner beans show that the concentration of vitamin C is higher in the seeds of immature legumes than in the pods. Mature, dry peas are devoid of the vitamin (Harris and Ray, 1933) (*cf.* vitamin C in cereals), but Shaw and Pascoe (1949) reported the presence of vitamin C in dry seeds of the broad bean.

Nicotinic acid. According to Terroine and Desveaux-Chabrol (1947), 96 per cent. of the total nicotinic acid in the mature, dry seeds of beans is in the cotyledons.

Leafy Vegetables

Carotene. The values of Munsell and Kennedy (1935) show that the concentration of carotene in green outer leaves of lettuce is much higher than that in white inner leaves, and according to Bartlett, Cotton, Henry and Kon (1938) the concentration in leaves of thousand-headed kale is higher than in stalks. In cooked broccoli Booher and Marsh (1941) found evidence that the concentration was higher in leaves than in buds. Sheets, Leonard and Gieger (1941) reported that the concentration of carotene was much higher in green outer than in white inner leaf blades of cabbage, and in leaf blades than in leaf stalks of spinach.

In unblanched celery Wilcox and Galloway (1951) found that the leaves were much richer than the stalks, and that outside leaves were richer than inside leaves, and outside stalks than inside stalks.

B vitamins. Flavier and Genevois (1939) reported that the concentration of riboflavin was much the same in heart and outer leaves of cabbage, but that the concentration of vitamin B_1 was higher in the former than in the latter. Wood, Collings, Stodola, Burgoin and Fenton (1946) confirmed the conclusion with respect to vitamin B_1 but found that heart were slightly richer in riboflavin than outer leaves. The concentrations of both vitamins decreased steadily from the centre to the periphery of the plant. In lettuce Flavier and Genevois (1939) found little difference between outer and heart leaves with respect to vitamin B_1 or riboflavin concentration. According to Jones, Wood, Phillips, Fenton and Harris (1944), the concentrations of vitamin B_1 and riboflavin were higher in the buds of commercially frozen broccoli than in the stalks.

The results of Robbins, Hervey and Stebbins (1950; 1951) show that, in comparison with micro-organisms and animals, higher plants are very poor sources of vitamin B_{12}, and that most of the vitamin B_{12} present is in the roots. In cabbage, broccoli, kale, celery and leeks the leaves were devoid of vitamin B_{12} and the stems contained no more than a trace.

Vitamin C. (1) *Cabbage and Brussels sprouts.* In a series of comparisons between heart and outer leaves of market-purchased cabbage, Chappell (1940) found that the concentration of vitamin C was higher in the heart. Robinson and Courtice (1940), however, found that green leaves just under the outermost leaves were richer than the middle leaves or the innermost leaves, and Sheets *et al.* (1941) that the blades of green, outer leaves of fresh cabbage were richer than the blades of white, inner leaves. In the samples analysed by Lampitt *et al.* (1943), green, outer leaves were richer than heart leaves, but heart leaves were, in two out of three instances, richer than leaves immediately beneath the outermost leaves.

Le Riche (1946–47*b*) compared green and white leaves of cabbage in two successive seasons and found the average concentration of vitamin C significantly higher in green than in white leaves in the first year, but slightly higher in white than in green leaves in the second year. Le Riche stated that the weather was hotter and drier and growth was slower in the second than in the first year, and suggested that the difference in weather conditions between the two seasons may have influenced the distribution of the vitamin.

Higher concentrations in green outer leaves than in heart and core were found in most of the cabbage heads studied by Beckley and Notley (1941), Olliver (1947) and Branion, Roberts, Cameron and McCready (1948), but Hallsworth and Lewis (1949) found a higher concentration in the heart and core than in the outer leaves, and Branion *et al.* (1948) state that the concentration of ascorbic acid in the outer green leaves was much reduced if they were faded. The studies of Beckley and Notley (1941),

Wood *et al.* (1946), Olliver (1947), Branion *et al.* (1948) and Hallsworth and Lewis (1949) were more detailed than those of other workers, and their results show clearly that there is a zone of minimum vitamin C concentration between the outer leaves and the heart.

Lampitt *et al.* (1943) and Hallsworth and Lewis (1949) found a higher concentration in leaf blades than in midribs, but Le Riche (1946–47*b*) found no appreciable difference between the concentrations in the midrib and the leafy tissue, and Wood *et al.* (1946) reported higher values for the rib than for the blade, at any rate in outer green leaves.

From the available evidence it appears that the concentration of vitamin C in the cabbage is at a minimum in the layers roughly midway between the periphery and the core. The outer leaves and the heart and core are the richest parts of the head, the first being frequently but not invariably the area of maximum concentration. Wilting reduces the vitamin C content of the outer leaves.

In Brussels sprouts Olliver (1936) found no marked differences in vitamin C concentration between one part of the sprout and another, but the value obtained for the heart leaves was slightly higher and for the stem slightly lower than the values for the inner and outer leaves. A slightly higher concentration in heart than in outer leaves was recorded by Chappell (1940).

(2) *Broccoli and Cauliflower.* In fresh broccoli Wheeler, Tressler and King (1939) and Fujita and Ebihara (1939) found a higher concentration of vitamin C in the buds than in the stalks, and Lampitt *et al.* (1943) a slightly higher concentration in the heads than in the leaves. According to Fujita and Ebihara (1939) the concentration is higher in the mesophyll tissue of the leaves than in the veins. With commercially frozen broccoli it has been found that the concentration of vitamin C in the stalks is higher than in the buds (Barnes and Tressler, 1943 ; Jones *et al.*, 1944), suggesting that a redistribution of the vitamin occurs during processing, probably when the vegetable is scalded before freezing.

In fresh cauliflower Wheeler *et al.* (1939) reported that the concentration of vitamin C was, on the average, slightly higher in the buds than in the stalks, and Chappell (1940) that the concentration was much higher in the buds than in the leaves. Beckley and Notley (1941) made a detailed study of a cauliflower plant and found that the concentration was higher in the outer leaves than in the head ; within the head the stalks of the inner buds were much richer than the buds themselves, but the outer buds were slightly richer than their stalks.

(3) *Spinach, Kale, Seakale, Lettuce and Watercress.* In spinach, Olliver (1936) reported that the concentration of vitamin C in small centre leaves was higher than in a medium-sized inner leaf or a large outer leaf from the same plant. Stems were much poorer in vitamin C than leaves, a finding confirmed by Tressler, Mack and King (1936), Ijdo (1936) and Sheets *et al.* (1941). Olliver (1936) bisected single spinach leaves by cutting along or at right angles to the midrib and analysed the halves separately. The results showed that the distribution of the vitamin in a single leaf was fairly even, but that the concentration varied considerably from one leaf to another. Fujita and Ebihara (1939) found that the concentration of vitamin C was much higher in the mesophyll tissue of the leaf than in the veins.

The results of Chappell (1940) showed that the concentration of vitamin C was higher in inner leaves of curly kale than in outer leaves, which in turn were richer than heart leaves. Still lower values were obtained for midribs from the lower ends of outer leaves. Murphy (1944) also reported higher values for inner than for outer leaves of kale, but Werder and Antener (1938) found outer leaves richer than inner leaves.

The analysis of seakale made by Chappell (1940) showed no great difference in vitamin C concentration between outer leaves, inner leaves, and the heart cluster, but there was a slight tendency for the values to be higher at the centre than at the periphery of the plant.

In lettuce Werder and Antener (1938) found that green leaves were richer than white heart, and Le Riche (1946–47*a*), who analysed a cabbage-type lettuce, that green leaves were richer than white leaves, but Lampitt *et al.* (1943) found that the concentration was higher in the heart of lettuce than in the outer leaves. Sheets *et al.* (1941) reported that the concentration of vitamin C was much higher in the blades than in the stalks of the leaves.

In watercress the concentration of vitamin C in the leaves greatly exceeded that in the stalks (Lampitt *et al.*, 1943).

(4) *Celery and Rhubarb.* Several investigators have shown that the leaves of celery are much richer in vitamin C than the stalks (Osterman, 1938 ; Chappell, 1940 ; Wilcox and Galloway, 1951). Chappell (1940) found no appreciable difference between the upper and lower ends of a stalk, between inner and outer stalks, or between stalks and heart, and Lampitt *et al.* (1943) found almost no difference between green and white stalks. Wilcox and Galloway (1951), however, found higher concentrations in the outside than in the inside leaves and in the inside than in the outside stalks of unblanched celery. Osterman (1938) also reported higher values for inside than for outside stalks of celery.

In rhubarb also it was found that the concentration of vitamin C was much higher in the leaves

than in the stalks (Chappell, 1940). The available evidence shows that the concentration is higher at the top of the stalk than at the base (Chappell, 1940; Brown, Schuele and Fenton, 1941), and Brown *et al.* (1941) stated that the skin was slightly richer than the interior of the stalk.

(5) *Asparagus.* The concentration of vitamin C decreased from the tip down the stem in fresh, mature shoots (Olliver, 1936; 1938; Clifcorn and Heberlein, 1944), and also in immature shoots before the tips had become green, as well as in stored asparagus (Olliver, 1938).

(6) *Leek and Onion.* In two tests Chappell (1940) found that the concentrations of ascorbic acid at the top and at the base of leek stems were almost the same, but in a third comparison the concentration was found to be higher at the top.

In bulbs of 10 varieties of onion the concentration of ascorbic acid was higher in the central than in the peripheral tissue (Murphy, 1941).

Vitamin E. There is evidence that in kale the concentration of tocopherols is much higher in the leaves than in the stems (Brown, 1953).

Root Vegetables

Carotene. The results of Booth (1951*a*) for 16 varieties of carrot show clearly that the concentration of total carotenoids in the cortex (phloem) is much higher than that in the core (xylem). Harper and Zscheile (1945) found in the one variety studied by them that cross-sectional slices taken from the tip and centre of a root were alike in total carotenoid concentration, but that those from the top were 50 per cent. richer. In centre slices the outer phloem was richer than the inner phloem.

B vitamins. Streightoff, Munsell, Ben-Dor, Orr, Leonard, Ezekiel and Koch (1946) found evidence that the concentrations of vitamin B_1, riboflavin and nicotinic acid were much higher in the portion of the carrot root removed by machine peeling than in the remainder of the root. Streightoff, Munsell, Ben-Dor, Orr, Cailleau, Leonard, Ezekiel, Kornblum and Koch (1946) stated also that the concentrations of riboflavin and nicotinic acid were higher in the peelings of potatoes than in the peeled tuber. Teply *et al.* (1942), however, found a slightly lower concentration of nicotinic acid in potato peelings than in peeled tubers.

Meiklejohn (1943) concluded that vitamin B_1 was concentrated in the centre, not in the skin layer of the potato tuber, and at the bud end, not at the stem end. During storage there was a loss from the centre of the tuber, particularly in spring after sprouting had begun.

According to Toepfer *et al.* (1951), the concentration of folic acid is higher in potato peelings than in the remainder of the tuber.

Vitamin C. In carrots, according to Beckley and Notley (1941), the concentration of ascorbic acid was slightly higher at the top end of the root than at the middle or tip, but in parsnips the concentration of vitamin C was higher in the tip than in the upper portion of the root (Mayfield and Richardson, 1940; Brown and Fenton, 1942). Olliver (1941) found that the concentration was lower in the peel of old parsnips than in the remainder of the root, and Brown and Fenton (1942) that the cortex of fresh parsnips was poorer than the medulla.

Much evidence is available concerning the distribution of vitamin C in the potato tuber, showing for the most part that the concentration tends to be lower in the skin or peel than in the interior of both new and old tubers (Paech, 1938; Olliver, 1941; Esselen, Lyons and Fellers, 1942; Murphy, Dove and Akeley, 1945; Branion, Roberts and Cameron, 1947). Chappell (1940), however, reported a slightly higher concentration at the periphery than at the centre of new Cyprus potatoes, and Rolf (1940) and Lampitt, Baker and Parkinson (1945) could find no appreciable difference between the concentrations in the periphery and interior of potatoes during storage. Lampitt *et al.* (1945) suggested that oxidation of vitamin C in the peel during sampling may have been responsible for the finding, by other workers, of lower values in the peel than in the interior; but this explanation does not appear to be applicable to Paech's (1938) work, where special precautions were taken to avoid error from oxidation, or to that of Branion *et al.* (1947), whose conclusions were based on the difference between values for unpeeled and peeled tubers as well as on direct analysis of peel. Lampitt *et al.* (1945) took relatively thick ($\frac{1}{8}$-inch) samples of peel for analysis and it is possible, as they themselves suggest, that their samples of peel included too much of the interior of the tuber for a small difference between skin and interior to be detected.

Evidence is available also that the concentration of vitamin C may be higher at the bud end of the tuber than at the stem end. Such a relation was found in stored and in fresh potatoes (Rolf, 1940), in stored, sprouting potatoes (Smith and Gillies, 1940), and in 21 out of 26 samples of potatoes in the early stages of storage (Baird and Howatt, 1948). Lampitt *et al.* (1945) obtained inconclusive results in tests on one variety of new and two varieties of old potatoes but found that in sprouted potatoes the concentration of vitamin C was often greater in the sprouts and in the peel surrounding the eyes than in the remainder of the peel or in the interior of the potato. Paech (1938) and Esselen *et al.* (1942) could find no appreciable difference between the concentrations of vitamin C in the outer, intermediate, and inner portions of peeled tubers.

Fungi

No appreciable difference in ascorbic acid concentration was found by Chappell (1940) between stems, gills, peel and white flesh of the mushroom.

General Conclusions

The available evidence shows that the concentration of carotene is higher in the leaves than in the stalks of a number of plant species and is higher in green, outer leaves and stalks than in inner leaves and stalks. In the root of the carrot the concentration is much higher in the outer tissue than in the core.

Information about members of the vitamin B complex is too meagre for many conclusions to be reached, but it appears that the concentration of vitamin B_1 may be lower, and the concentrations of riboflavin and folic acid higher, at the periphery than in the interior of the potato tuber.

In many species of leafy vegetables there is a tendency for the concentration of vitamin C to be higher in green, outer leaves than in inner leaves, and in areas of active growth, such as the heart or core or the tips of shoots, than in more mature tissues. Leaf blades tend to be richer than midribs, petioles and stems, and the mesophyll tissue of the blades than the veins; buds are often richer than their stalks. The relative extent to which these tendencies are demonstrated varies from one species to another, and even between individual plants of the same species.

TABLE 3

CONCENTRATION OF VITAMIN C IN FRESH TISSUES OF SOME COMMON VEGETABLES *

Vegetable	Tissue or part of vegetable	Vitamin C (mg. per 100 g.) Sample 1	Sample 2	Sample 3	Authority
Asparagus	Tip	83·3	45·0	165·4	Olliver (1936)
	Middle green stem	37·5	23·7	71·7	
	White stem	17·0	8·0	25·6	
Beans, runner	Seeds	50			Lampitt *et al.* (1943) †
	Pods	29			
Broccoli, 4 varieties	Blossoms		av. 146		Wheeler *et al.* (1939) †
	Stems		av. 109		
Cabbage	Outer green leaves	85·7	63·0	104·6	Beckley and Notley (1941)
	Curled green leaves	68·9	49·4	55·2	
	White leaves	45·2	46·0	32·5	
	Heart leaves	78·0	65·7	55·0	
	Core	77·9	66·3	56·7	
Celery, 3 varieties in 4 seasons	Outside stalks	Range 7·8 to 11·1			Wilcox and Galloway (1951)
	Inside stalks	,, 7·7 to 21·6			
	Inside leaves	,, 26·7 to 52·2			
	Outside leaves	,, 25·9 to 108·7			
Potato, 6 tubers	Central portion		av. 13·1		Esselen *et al.* (1942) †
	Median portion		av. 12·9		
	Epidermal portion		av. 13·4		
	Skin		av. 10·4		
Rhubarb	Base of stalk	10·6	10·3		Chappell (1940)
	Middle of stalk	10·7	10·3		
	Top of stalk including leaf stem	17·5	14·4		
	Leaf	42·0	40·8		
Spinach, 4 samples	Leaves	Range 32·1 to 60·0			Olliver (1936)
	Stems	,, 8·8 to 16·4			

* Values based on chemical estimation of ascorbic acid.
† Values stated to have been checked by biological tests or H_2S reduction.

In immature legumes the concentration of vitamin C is higher in the seeds than in their pods. In the subterranean parts of plants studied, namely, parsnip roots and potato tubers, the concentration of vitamin C tends to be higher in the interior than at the periphery. In the mushroom there seems to be an even distribution of vitamin C.

Discussion

The information given in the preceding sections covers numerous aspects of vitamin distribution and includes a number of detailed studies, but much more attention has been paid to some foods than to others, and interest has usually centred round a relatively small number of the vitamins.

Some of the main findings are briefly discussed below, but no attempt has been made to include all aspects of the subject. In some instances the evidence is not as yet sufficiently detailed or well enough confirmed to justify further consideration; in others a full discussion of the facts is already available in reference works on the vitamins.

Conditions possibly affecting Distribution

Cereals. It is not certain where the B vitamins of cereal grains are originally formed. For wheat and oats there is evidence which suggests that vitamin B_1 is not formed *in situ* in the kernels, but is translocated to them from the leaves (see Holman, 1945–46, for references). There is evidence also to show that light is required for the synthesis of vitamin B_1 in plants, and that in the tomato plant the vitamin is translocated from the leaves to the growing point of the shoot (see Hinton, 1947, for references).

It can be seen from Table 1 (p. 279) that, although the concentration of vitamin B_1 in the scutellum and of vitamin B_1 and nicotinic acid in the aleurone layer may become extremely high in mature kernels, the endosperm of cereals is extremely poor in those vitamins when compared with the remainder of the grain or, on a dry matter basis, with many other vegetable tissues (*cf.* Cheldelin and Williams, 1942). The concentration tends to be higher in the outer than in the inner endosperm and may be relatively high in cells adjacent to the aleurone layer and scutellum.

The findings just quoted suggest that water-soluble vitamins may diffuse from the centre of the grain towards the periphery during dehydration of the kernel in the final stages of ripening. The hypothesis was originally proposed by Sherwood, Nordgren and Andrews (1941), and has received some support from the work of Pollock and Geddes (1951). The latter workers, studying the distribution of vitamin B_1 and riboflavin in kernels of wheat at different stages of maturity, found evidence of some movement of vitamins away from the endosperm. Yet the concentrations in the cells of the aleurone layer, round the crease and in the scutellum were independent of the stage of maturity.

Discussing the probable role of vitamin B_1 in the scutellum, Hinton (1947) pointed out that the scutellum is usually considered to be the first leaf of the embryonic plant and may, therefore, like the growing points of plant stems, have a high vitamin B_1 requirement during its development. He suggested that vitamin B_1 might later accumulate when the scutellum passes out of the meristematic condition.

It has long been recognised that the aleurone layer and the columnar epithelium of the scutellum play an important part during the germination of cereals by producing enzymes required for the digestion of the endosperm, and that the soluble nutrients formed pass through the scutellum to the embryo (see, *e.g.*, Percival, 1921). Whether the high concentrations of B vitamins stored in the scutellum and aleurone layer have any special significance in the processes of germination is not clear from existing evidence. It is not likely that vitamin B_1 is required for the conversion of starch to maltose. Hinton (1947) found that the concentration of vitamin B_1 in the scutellum decreased after germination, but not during the early stages. He concluded that vitamin B_1, although probably not important for the mobilisation of carbohydrates, may be required for the development of the growing tips of the seedling, before vitamin B_1 has been synthesised in the leaves in sufficient amount to be available for transport. The work of Burkholder and McVeigh (1942) and Klatzkin, Norris and Wokes (1948) shows that synthesis of a number of B vitamins may take place during the germination of cereal grains, but it appears that vitamin B_1 is synthesised then to a less extent than many other B vitamins, if at all. Vitamin C is synthesised during germination (see, *e.g.*, Harris and Ray, 1933).

The vitamin E in cereal grains is concentrated in the germ in association with the lipids. Since it is generally believed that plants have no mechanism for the transportation of fat-soluble materials (see, *e.g.*, Rosenberg, 1942) it seems probable that vitamin E is formed *in situ* in the kernel.

Fruits and Vegetables. β-Carotene is invariably present in green tissues, being one of the plastid pigments of plants, and its formation, like that of the chlorophylls, is stimulated by light (see, *e.g.*, Rosenberg, 1942), so it is not surprising that green outer parts of plants should usually be richer in carotene than paler, inner tissues.

The presence of high concentrations of carotenoids in the root of the carrot seems remarkable because chlorophyll is absent and the tissues

receive no light. It seems unlikely that the carrot plant can transport carotenoids from the leaves to the root, since these pigments are insoluble in water (*cf.* p. 287, col. 2, paragraph 3). It therefore appears probable that the carotenoids are formed *in situ* in the root either by total synthesis or from a water-soluble precursor transported from the leaves. The recent finding of Booth (1951*b*) that synthesis of carotenoids may take place during storage in carrot roots detached from the leaves supports that view.

It is not proposed to give a full account of the conditions which may affect the distribution of vitamin C in plants, since the subject has recently been reviewed by Mapson (1954). The evidence shows that vitamin C is present in all plant tissues except seeds and woody parts, but it is not yet clear whether it is synthesised by all tissues. The fact that stalks are frequently poorer in vitamin C than leaves may be attributed, in part at least, to the presence of more lignified tissue in the former than in the latter. The concentration of the vitamin in a particular tissue probably depends not only on synthesis there and diffusion to or from other tissues, but also on the rate at which the vitamin is destroyed by oxidation. That a high concentration may be required during intense metabolic activity is suggested by the fact that tissues are often richer when young and actively growing than when mature.

There is much evidence that light stimulates the production of vitamin C in plants. In the cabbage, the concentration of the vitamin in the leaves has been found to increase after exposure of the plant to sunlight (see Hallsworth and Lewis, 1949). A similar increase has been reported in fruits such as the tomato and strawberry (see, *e.g.*, Robinson, 1949; Somers, Hamner and Kelly, 1950). The tendency for outer leaves to be richer in vitamin C than middle leaves, as in the cabbage, may thus be related to the amount of light received before harvest. The presence of chlorophyll is apparently not necessary for synthesis of the vitamin (*cf.* vitamin C in asparagus, p. 285).

Practical Applications of Knowledge about Distribution

Information about the distribution of vitamins in the constituent tissues of plants has a number of possible applications, some of which are listed and will now be briefly discussed.

Applications in food analysis. Consideration must be given to the distribution of vitamins if representative samples of food are to be obtained for analysis, particularly when the size of the sample taken is small relative to that of the whole tissue being examined. With cereal grains, which are small, little difficulty is likely to be experienced, even though the distribution within the grain is uneven, provided that the sample is finely ground and none of the resulting powder is discarded before mixing. Satisfactory sampling of fruits and vegetables is frequently difficult. No single method is generally applicable, owing to the wide differences in morphology and vitamin distribution between individual foods in those classes. In selecting methods for particular foods the information contained in the previous sections of the present review should be taken into account.

Applications in food preparation and processing. In many established methods of food preparation for human consumption particular tissues are discarded. From a knowledge of vitamin distribution in foods it can be judged whether in any particular instance large amounts of potentially available supplies are being lost. Thus, little loss of vitamin C probably occurs in the peeling of potatoes, since the skin usually has a lower concentration than the flesh, but the rejection of tissues which are outstandingly rich in vitamin C such as the outer leaves of vegetables or the skin of fruits may mean the loss of considerable amounts.

In the processing of cereals, loss of vitamins is unimportant if no particular tissue of the kernel is preferentially removed during milling; in the manufacture of oatmeal (see Holman and Godden, 1947) or the production of wholemeal flours, for example, there is no fractionation. But in the preparation of rice and of white flours from wheat, rye and maize, much of the bran and germ, which are particularly rich in a number of B vitamins, are excluded and the concentration of B vitamins in the milled product is consequently low.

With wheat, the identification of the site of maximum concentration of vitamin B_1 in the grain has stimulated interest in recent years in the possibility of retaining more of the vitamins in white wheaten flour without simultaneously raising the fibre content of the flour or adversely affecting its keeping and baking qualities. Modifications of the milling process have been described, designed to direct more of the scutellum into the flour and to extract more of the vitamin B_1 from the bran layers without increasing the fibre content (see Holman, 1945–46, for references and further discussion).

EVIDENCE CONCERNING FOODS OF ANIMAL ORIGIN

The distribution of vitamins in the tissues and secretions of animals has been widely investigated, and there is now a large amount of information about a number of different species. The information summarised in the following sections is restricted to findings on animal products commonly

used as human food. Others that are of physiological interest and have some bearing on the interpretation of the present data are beyond the scope of this review.

The information given below is confined to tissues of normally fed animals, as produced commercially for human food, and includes only a few references to the effects of undernutrition and of specific vitamin deficiencies on the composition of the tissues.

The vitamins discussed here comprise vitamins A and D, the vitamin B complex and vitamins C and E, for all are found in animal products. Vitamin D is abundant only in certain species of fish, and information about its distribution in many products is meagre.

Beef, Mutton and Pork

Vitamin A. The livers of the ox, sheep and pig are all rich in vitamin A (see, *e.g.*, Gillam, 1938; Booher and Marsh, 1941; Moore and Payne, 1942; McGillivray, 1949). Small amounts of carotene may accompany vitamin A in the liver, especially in beef liver (see, *e.g.*, von Euler and Virgin, 1932; Moore and Payne, 1942). In beef, there is evidence that some vitamin A activity is present also in kidney, heart and suet (Booher and Marsh, 1941), and in the fat covering of a rib cut (Hewston, Dawson, Alexander and Orent-Keiles, 1948). According to Booher and Marsh (1941), in all three species lean muscle is devoid of measurable activity, but Munsell (1940) concluded from a study of the literature that lean muscle of beef and pork contains small amounts of the vitamin.

Vitamin B_1. Higher concentrations of vitamin B_1 in beef heart and kidney than in liver have been recorded by Mickelsen, Waisman and Elvehjem (1939*a*), Cheldelin and Williams (1942), and Scheid, Bennett and Schweigert (1953), and a higher concentration in beef liver than in skeletal muscle by Mickelsen *et al.* (1939*a*), Cheldelin and Williams (1942) and McIntire, Schweigert, Herbst and Elvehjem (1944). According to Fornaroli (1951) the concentration is higher in the ventricles and intraventricular septum of beef heart than in the auricles.

In mutton the concentration appears to be slightly higher in heart than in liver (McGillivray, 1949; Scheid *et al.*, 1953); both heart and liver are richer in vitamin B_1 than skeletal muscle (Pyke, 1940; McGillivray, 1949).

The skeletal muscles of the pig are particularly rich in vitamin B_1 compared with those of other mammals (see Mickelsen *et al.*, 1939*a*; Pyke, 1940) and in this animal the concentration of the vitamin is higher in the skeletal muscles than in the liver (Mickelsen *et al.*, 1939*a*; Miller, Pence, Dutcher, Ziegler and McCarty, 1943; Heinemann, Ensminger, Cunha and McCulloch, 1946; Erikson and Boyden, 1947*a*; Hewston *et al.*, 1948; Hartzler, Ross and Willett, 1949).

There is some evidence that the muscles of pork ham and loin are slightly richer than those of the shoulder (see, *e.g.*, Miller *et al.*, 1943; Rice, Daly, Beuk and Robinson, 1945; Heinemann *et al.*, 1946; Erikson and Boyden, 1947*a*); but Hartzler *et al.* (1949) obtained slightly higher values for shoulder than for loin.

Pyke (1940) showed that vitamin B_1 is not distributed evenly between individual skeletal muscles of the pig; the highest concentration was found in psoas muscle and the lowest in the muscles of the fore leg. The concentration in psoas muscle was consistently higher than in longissimus dorsi muscle. Tongue was poorer in vitamin B_1 than any of the skeletal muscles studied. The concentration was higher in the ventricles than in the auricles of the pig's heart.

Brady, Peterson and Shaw (1944*a*) reported that the concentration of vitamin B_1 was slightly higher, on the average, in the lumbar than in the thoracic part of longissimus dorsi muscles from 8 pork loins. Rice *et al.* (1945) estimated B vitamins in 24 skeletal muscles from each of several carcases and found that muscles rich in vitamin B_1 were often rich also in nicotinic acid, but relatively poor in riboflavin and pantothenic acid (see Table 5 for results from one carcase). Muscles which were rich in vitamin B_1 in one animal tended to be rich also in other animals. Of the muscles studied, the longissimus dorsi, gluteus profundus and semimembranosus were among the richest in vitamin B_1, and the brachialis, obliquus internus and deltoideus among the poorest. Rose and Peterson (1948) found much less variation in the concentration of vitamin B_1 between 10 samples of longissimus dorsi muscle from one carcase than between samples from 11 different carcases.

Heinemann *et al.* (1946) found that, of the pork tissues studied by them, loin and ham were the richest, usually followed by shoulder, heart, liver and kidney. The values of Scheid *et al.* (1953) for the concentrations in organs also are higher on the average for heart than for kidney or liver (see Table 5, p. 291).

Riboflavin. Beef liver is richer in riboflavin than kidney or heart (Schormüller, 1939*b*; Cheldelin and Williams, 1942; Brady *et al.*, 1944*b*; Scheid *et al.*, 1953), and much richer than skeletal muscle (Lunde, Kringstad and Olsen, 1938; Mickelsen *et al.*, 1939*b*; Cheldelin and Williams, 1942; Cheldelin, Woods and Williams, 1943; McIntire, Schweigert, Herbst and Elvehjem, 1944; Brady *et al.*, 1944*b*; Hewston *et al.*, 1948).

Brady *et al.* (1944*b*) analysed 20 muscles from each of 12 beef carcases and found marked differences in riboflavin concentration between different

muscles (see Table 4). The muscles with the highest average concentrations were the transversus abdominis, trapezius thoracalis, psoas major and deltoideus, and those with the lowest average concentrations were semitendinosus, serratus dorsalis, longissimus dorsi and serratus thoracis. Differences in riboflavin concentration were much less between cuts of beef, each of which contained a number of muscles, than between individual muscles. Cover, Dilsaver, Hays and Smith (1949) found higher average values for biceps femoris and semimembranosus muscles than for semitendinosus and longissimus dorsi muscles, an observation which is in agreement with the findings of Brady *et al.* (1944*b*) given in Table 4.

With mutton the concentration of riboflavin is higher in liver than in kidney or heart (McGillivray, 1949; Scheid *et al.*, 1953), or skeletal muscle (Lunde *et al.*, 1938; McGillivray, 1949).

In pork tissues the concentration is higher in liver than in heart or kidney (Peterson, Brady and Shaw, 1943; Heinemann *et al.*, 1946; Scheid *et al.*, 1953), and much higher in liver than in skeletal muscle (Lunde *et al.*, 1938; Peterson *et al.*, 1943; Miller *et al.*, 1943; Heinemann *et al.*, 1946; Erikson and Boyden, 1947*a*; Hewston *et al.*, 1948; Hartzler *et al.*, 1949). There is some evidence that ham and shoulder muscles may be richer than loin muscle (see, *e.g.*, Miller *et al.*, 1943; Rice *et al.*, 1945; Heinemann *et al.*, 1946; Erikson and Boyden, 1947*a*; Hartzler *et al.*, 1949), but Jackson, Crook, Malone and Drake (1945) recorded slightly higher values, on the average, for loins than for butts.

Higher concentrations in triceps brachii and psoas major muscles of pork than in longissimus dorsi, adductor and semitendinosus muscles were found by Peterson *et al.* (1943), and higher average values were reported by Brady *et al.* (1944*a*) for psoas major than for longissimus dorsi muscles in 10 loins. Brady *et al.* concluded that there are differences within the same muscle, as well as between different muscles from the same animal and between the same muscles of different animals fed on the same diet. Rice *et al.* (1945) found differences in riboflavin concentration between individual pork muscles (see Table 5) and Cover *et al.* (1949) reported higher values for semimembranosus and biceps femoris than for longissimus dorsi muscles.

Nicotinic acid. Among beef tissues liver is richer in nicotinic acid than heart or kidney (Bandier, 1939; Waisman, Mickelsen, McKibbin and Elvehjem, 1940; McIntire, Waisman, Henderson and Elvehjem, 1941; Dann and Handler, 1942; Cheldelin and Williams, 1942; Scheid *et al.*, 1953) or skeletal muscle (Bandier, 1939; Waisman *et al.*, 1940; McIntire *et al.*,

TABLE 4

CONCENTRATION OF B VITAMINS IN THE LEAN PART OF FRESH TISSUES OF BEEF AND MUTTON

* Average values of Scheid *et al.* (1953) for vitamin B_1, riboflavin and nicotinic acid, and of Schweigert and Guthneck (1953) for pantothenic acid, in tissues of the same 10 commercial carcases (pantothenic acid after storage at — 10° C.).

† Average values of Brady *et al.* (1944*b*) for individual muscles of 12 Hereford yearlings.

‡ Values of McGillivray (1949) for tissues of a mature Romney × Southdown ewe.

1941 ; Cheldelin and Williams, 1942 ; Dann and Handler, 1942 ; Hale, Davis and Baldwin, 1942 ; Hewston *et al.*, 1948). According to Bandier (1939) the concentration of the vitamin is slightly higher in the cortex of the kidney than in the medulla.

Lamb's liver is richer in nicotinic acid than kidney or heart (McGillivray, 1949 ; Scheid *et al.*, 1953). All three organs are richer than skeletal muscle (McIntire *et al.*, 1941 ; McIntire, Schweigert, Herbst and Elvehjem, 1944 ; McGillivray, 1949).

In pork the concentration is higher in liver than in kidney or heart (Bandier, 1939 ; Waisman *et al.*, 1940 ; McIntire *et al.*, 1941 ; Scheid *et al.*, 1953) or skeletal muscle (Bandier, 1939 ; Waisman *et al.*, 1940 ; McIntire *et al.*, 1941 ; Dann and Handler, 1942 ; Erikson and Boyden, 1947*a* ; Hewston *et al.*, 1948 ; Hartzler *et al.*, 1949).

The available evidence does not show any clear, consistent difference in nicotinic acid concentration between loin and ham muscles (see, *e.g.*, Waisman *et al.*, 1940 ; McIntire *et al.*, 1941 ; McIntire, Schweigert, Henderson and Elvehjem, 1943 ; Jackson *et al.*, 1945 ; Erikson and Boyden, 1947*a*). Hartzler *et al.* (1949) found a slightly higher average concentration in loin than in shoulder, but the values of Erikson and Boyden (1947*a*) are, if anything, slightly higher for shoulder than for loin. Rice *et al.* (1945) found differences in nicotinic acid concentration between shoulder, loin and ham muscles in individual carcases, but the differences were not consistent from one carcase to another.

The results of Rose and Peterson (1948) show much less variation between different samples of longissimus dorsi muscle from the same animal

TABLE 5

CONCENTRATION OF B VITAMINS IN THE LEAN PART OF FRESH PORK TISSUES

Tissue	Vitamin B_1 (mg. per 100 g.)	Riboflavin (mg. per 100 g.)	Nicotinic acid (mg. per 100 g.)	Pantothenic acid (mg. per 100 g.)

* Average values of Scheid *et al.* (1953) for vitamin B_1, riboflavin and nicotinic acid, and of Schweigert and Guthneck (1953) for pantothenic acid, in tissues of the same 10 commercial pigs (pantothenic acid after storage at — 10° C.).

† Values of Rice *et al.* (1945) for one commercial pig. Numbers in brackets indicate the relative redness of the muscles, No. 1 being the least red and No. 24 the reddest.

than between samples from different animals. Cover *et al.* (1949) found higher average concentrations in semimembranosus and longissimus dorsi muscles than in biceps femoris muscle.

Pantothenic acid. In beef tissues, a higher concentration of the vitamin in liver than in kidney or heart was recorded by Cheldelin and Williams (1942), Waisman, Henderson, McIntire and Elvehjem (1942) and Schweigert and Guthneck (1953), and a higher concentration in liver than in skeletal muscle by Cheldelin and Williams (1942), Waisman *et al.* (1942), Cheldelin *et al.* (1943), Meyer, Hinman and Halliday (1947) and Schweigert and Guthneck (1953). Cover *et al.* (1949) found a higher average concentration in biceps femoris than in semimembranosus muscle, which in turn was richer than semitendinosus or longissimus dorsi muscle.

Lamb's liver is richer in pantothenic acid than heart (McGillivray, 1949) or kidney (Schweigert and Guthneck, 1953), and all three organs are much richer than skeletal muscle (Waisman *et al.*, 1942 ; McGillivray, 1949 ; Schweigert and Guthneck, 1953).

In the pig, there is evidence that the liver is richer in pantothenic acid than the kidney, heart or skeletal muscle (Waisman *et al.*, 1942 ; Schweigert and Guthneck, 1953). Rice *et al.* (1945) found considerable differences in concentration between individual muscles (see Table 5) and Cover *et al.* (1949) found higher concentrations in semimembranosus and biceps femoris muscles than in longissimus dorsi muscle, a finding supported by the data of Rice *et al.* (1945) (Table 5).

Vitamin B_6. In beef tissues the concentration is higher in liver than in kidney or heart (Henderson, Waisman and Elvehjem, 1941 ; Cheldelin and Williams, 1942 ; McIntire, Schweigert and Elvehjem, 1944) or skeletal muscle (Henderson *et al.*, 1941 ; Cheldelin and Williams, 1942 ; Atkin, Schultz, Williams and Frey, 1943 ; McIntire, Schweigert and Elvehjem, 1944).

Little evidence is available about tissues of mutton and pork. Henderson *et al.* (1941) found lamb's liver slightly richer in vitamin B_6 than muscle, and they and Atkin *et al.* (1943) reported a higher concentration in pork muscle than in pork liver.

Biotin. Beef liver is richer in biotin than beef heart (Cheldelin and Williams, 1942) and is much richer than skeletal muscles of the same species (Cheldelin and Williams, 1942 ; Cheldelin *et al.*, 1943). In carcases of mutton McGillivray (1949) found a higher concentration of biotin in liver than in heart. Both organs were much richer than skeletal muscle.

Folic acid. Beef liver is richer than beef kidney (Schweigert, Pollard and Elvehjem, 1946 ; Toepfer *et al.*, 1951), heart (Cheldelin and Williams, 1942 ; Toepfer *et al.*, 1951) or skeletal muscle (Cheldelin and Williams, 1942 ; Cheldelin *et al.*, 1943 ; Schweigert *et al.*, 1946 ; Toepfer *et al.*, 1951). For mutton and pork also, there is evidence that liver tissue is much richer in folic acid than muscle (Schweigert *et al.*, 1946 ; Toepfer *et al.*, 1951).

Vitamin B_{12}. In all three species the concentration of vitamin B_{12} is higher in liver than in kidney or heart (Scheid and Schweigert, 1954). Among beef tissues, liver and kidney are much richer in vitamin B_{12} than skeletal muscle (Scheid and Schweigert, 1951 ; Scheid, Andrews and Schweigert, 1952). Beef muscles and organs are richer in vitamin B_{12} than the corresponding tissues of pork (Register, Lewis, Thompson and Elvehjem, 1949 ; Scheid and Schweigert, 1954).

Vitamin B complex in general. From the evidence just given on the distribution of B vitamins in the ox, pig and sheep it can be seen that, in general, riboflavin, nicotinic acid, pantothenic acid, vitamin B_6, biotin, folic acid and vitamin B_{12} are present in higher concentrations in the liver than in the kidneys, heart or skeletal muscles, but it should be noted that the amount of information available about some of the B vitamins is small.

The distribution of vitamin B_1 is less consistent. In cattle and sheep the liver, though richer in vitamin B_1 than the skeletal muscles, appears to be somewhat poorer in it than the heart and, in cattle, the kidney. In the pig, the concentration is usually higher in the skeletal muscles than in the heart, liver or kidney.

Individual muscles from the same carcase show wide differences in riboflavin in beef and in vitamin B_1, riboflavin, and nicotinic and pantothenic acids in pork, and there is some evidence in the pig of variation in vitamin B_1 concentration within a particular muscle.

In a comprehensive study of paired muscles of beef and pork, Cover, Dilsaver and Hays (1948) showed that the concentrations of vitamin B_1, riboflavin, and nicotinic and pantothenic acids in muscles from one side of a carcase do not differ significantly from the concentrations in the corresponding muscles from the other side of the same carcase.

The concentrations of B vitamins present in nuclei which had been separated by fractional centrifuging from disintegrated, dry, beef heart tissue, were compared by Isbell, Mitchell, Taylor and Williams (1942) with the concentrations in the whole tissue. Their results showed that the concentrations of vitamin B_1, riboflavin, nicotinic acid, pantothenic acid and folic acid, when expressed on a dry matter basis, were 3 or 4 times higher in the nuclei than in the whole tissue, but that the concentration of pyridoxine in the two fractions was about the same and that of biotin twice as high in whole tissue as in nuclei.

Vitamin C. Of numerous different tissues of beef and mutton analysed by Giroud, Leblond, Ratsimamanga and Gero (1938) the adrenal and pituitary glands were richest in vitamin C. Liver, though poorer than those glands, was richer than kidneys, which in turn were much richer than skeletal muscle.

With pork, Bessey and King (1933) found that, of the tissues studied by them, the adrenal glands and corpus luteum were the richest in vitamin C. Giroud *et al.* (1938) analysed only the adrenal glands, liver and kidneys of pork, but found the distribution of vitamin C between those tissues like that in beef and mutton.

Vitamin D. The vitamin is present in the liver of all three species (see, *e.g.*, Daniel and Munsell, 1937; Waisman and Elvehjem, 1941), but relatively little information is available about its distribution in other tissues.

Vitamin E. The pioneer work of Evans and Burr (1925; 1927) showed that vitamin E is widely distributed in the animal body, but is not present in very great concentration in any particular organ or tissue. Vitamin E activity was demonstrated in liver, body fat and muscles of beef and pork, and in mutton fat. Karrer, Jaeger and Keller (1940) and Chipault, Lundberg and Burr (1945) confirmed the presence of tocopherols in pork fat, and Karrer *et al.* (1940) and Harris, Quaife and Swanson (1950) found a higher concentration of tocopherols in liver than in muscle of beef. Bratzler, Loosli, Krukovsky and Maynard (1950) analysed tissues of pigs which had received a diet low in vitamin E, with or without a supplement of vitamin E, and found that the concentration of tocopherols was usually highest in body fat and liver. Tocopherol supplements increased the concentration in all the tissues studied.

Rabbit

Since the rabbit differs from many other mammals, including those discussed in the previous section, in having clearly defined "red" and "white" muscles (see p. 298), it seems desirable to consider this animal separately. In many respects vitamin distribution in the rabbit resembles that in beef, mutton and pork tissues.

Vitamin A. There is evidence that the liver is rich in vitamin A (see, *e.g.*, Gillam, 1938; Edisbury, Morton, Simpkins and Lovern, 1938). The latter workers estimated that 95 per cent. of the total vitamin A of the carcase is in the liver and that the mammary gland of the female is the next most important source.

Vitamin B_1. Pyke (1940) found the concentration higher in red muscles (soleus and pectineus, than in white (vastus lateralis, gluteus maximus, gastrocnemius, longissimus dorsi, gracilis), and a higher concentration in heart muscle than in skeletal muscle.

Riboflavin. A higher concentration in spleen and adrenal glands than in liver, and in liver than in heart, kidney or muscle was recorded by Isikawa, Kawai and Kimura (1937). Schormüller (1939*a*) found red muscle richer in riboflavin than white muscle.

Nicotinic acid. The results of Dann and Handler (1942) show that rabbit liver is richer in nicotinic acid than kidneys, which in turn are slightly richer than leg muscle. The distribution between red and white muscles does not, however, appear to have been studied.

Pantothenic acid. Kaplan and Lipmann (1948) estimated the bound form of pantothenic acid (coenzyme A) in tissues and found the concentration greater in liver than in kidney or heart. All three organs were much richer than skeletal muscle.

Vitamin C. The results of Bessey and King (1933) and Giroud *et al.* (1938) show that the pattern of distribution resembles that in beef, mutton and pork tissues, the concentration of the vitamin being higher in liver than in skeletal muscle, but lower in liver than in adrenal glands.

Vitamin E. Hines and Mattill (1943) found that in normally fed rabbits the concentration of tocopherols was slightly higher in muscle than in liver, but that rabbits with a very high or low intake of the vitamin had a higher concentration in liver than in muscle.

Poultry

Vitamin A. The presence of vitamin A activity in the liver of the chicken and the turkey was demonstrated by Guilbert and Hinshaw (1934), but Booher and Marsh (1941) found no measurable activity in lean chicken muscle. Deuel, Hrubetz, Mattson, Morehouse and Richardson (1943) showed that the liver and body fat of the chicken contain both vitamin A and carotenoids.

Vitamin B_1. There is much evidence that the concentration of vitamin B_1 is higher in dark than in light muscles of the chicken (Booher and Hartzler, 1939; Mickelsen *et al.*, 1939*a*; Rice, Strandine, Squires and Lyddon, 1946; Campbell, Hiltz and Robinson, 1946; Millares and Fellers, 1949; Erdsiek, Kanapaux, Richmond, Weis and Bisbey, 1951) and turkey (Campbell *et al.*, 1946; Erikson and Boyden, 1947*b*), and that leg muscle is richer than breast muscle in both chicken (Cheldelin and Williams, 1942; Morgan, Kidder, Hunner, Sharokh and Chesbro, 1949) and turkey (Cook, Morgan and Smith, 1949). In the chicken, the concentration of vitamin B_1 has been reported to be higher in liver than in muscle (Campbell *et*

al., 1946 ; Millares and Fellers, 1949 ; Morgan *et al.*, 1949 ; Erdsiek *et al.*, 1951), gizzard (Millares and Fellers, 1949 ; Morgan *et al.*, 1949 ; Erdsiek *et al.*, 1951), heart or skin (Morgan *et al.*, 1949). In the turkey, Cook *et al.* (1949) found the concentration higher in liver than in gizzard or skin, but lower in liver than in heart. Rice *et al.* (1946) made detailed studies of the distribution of B vitamins in thirteen skeletal muscles and in several organs of three chickens and found that the concentration of vitamin B_1 was higher in liver than in gizzard or skin, but lower in liver than in heart and some skeletal muscles (see Table 6 for data from one chicken).

Riboflavin. Dark muscles are richer in riboflavin than light muscles in both chicken (Mickelsen *et al.* 1939*b* ; Rice *et al.*, 1946 ; Hewston *et al.*, 1948 ; Millares and Fellers, 1949 ; Erdsiek *et al.*, 1951) and turkey (Erikson and Boyden, 1947*b*), and leg muscle is richer than breast muscle in the chicken (Hodson, 1940 ; Cheldelin and Williams, 1942 ; Morgan *et al.*, 1949) and turkey (Cook *et al.*, 1949). The concentration has been reported to be higher in liver than in muscle in the chicken (Hodson, 1940 ; 1941 ; Rice *et al.*, 1946 ; Morgan *et al.*, 1949 ; Erdsiek *et al.*, 1951) and turkey (Erikson and Boyden, 1947*b* ; Cook *et al.*, 1949). There is also evidence that liver is richer than heart, gizzard or skin in the chicken (Hodson, 1940 ; Rice *et al.*, 1946 ; Morgan *et al.*, 1949 ; Erdsiek *et al.*, 1951) and turkey (Erikson and Boyden, 1947*b* ; Cook *et al.*, 1949).

Nicotinic acid. Light muscles of the chicken are richer in nicotinic acid than dark muscles (McIntire *et al.*, 1941 ; Rice *et al.*, 1946 ; Hewston *et al.*, 1948 ; Millares and Fellers, 1949 ; Erdsiek *et al.*, 1951), and breast muscle is richer than leg muscle in both chicken (Dann and Handler, 1941 ; 1942 ; Cheldelin and Williams, 1942 ; Denton, Kellogg and Bird, 1947 ; Rice, Squires and Fried, 1948 ; Morgan *et al.*, 1949) and turkey (Cook *et al.*, 1949). In both chicken and turkey liver has roughly the same concentration of nicotinic acid as breast muscle or light meat (Dann and Handler, 1941 ; 1942 ; Rice *et al.*, 1946 ; Denton *et al.*, 1947 ; Millares and Fellers, 1949 ; Morgan *et al.*, 1949 ; Cook *et al.*, 1949 ; Erdsiek *et al.*, 1951). It appears also that the liver is richer in nicotinic acid than heart, gizzard or skin in the chicken (Rice *et al.*, 1946 ; Millares and Fellers, 1949 ; Morgan *et al.*, 1949 ; Erdsiek *et al.*, 1951) and the turkey (Cook *et al.*, 1949), but Morgan *et al.* (1949) found skin in one case richer than liver.

TABLE 6

CONCENTRATION OF B VITAMINS IN THE LEAN PART OF FRESH CHICKEN TISSUES *

Tissue	Vitamin B_1 (mg. per 100 g.)	Riboflavin (mg. per 100 g.)	Nicotinic acid (mg. per 100 g.)	Pantothenic acid (mg. per 100 g.)
Liver	0·09	2·17	13·9	2·20
Heart	0·22	1·05	2·91	1·26

Peroneus longus (8)	0·10	0·12	5·83	0·24
Tibialis cranialis (7)	0·08	0·21	7·50	0·24

* Values of Rice *et al.* (1946) for tissues of a 4-month-old White Rock cockerel which had received a normal commercial diet.

† Numbers in brackets indicate the relative darkness in colour of the muscles, No. 1 being the lightest and No. 11 the darkest.

Pantothenic acid. Waisman *et al.* (1942) and Rice *et al.* (1946) found dark muscles of the chicken richer than light muscles, and Cheldelin and Williams (1942) and Pearson, Melass and Sherwood (1946) found a higher concentration in leg muscle than in breast tissue. Rice *et al.* (1946) noted that there was considerable variation in pantothenic acid concentration between the thirteen different muscles studied by them. They further found that liver was much richer than heart, gizzard, skin or any of the muscles. Pearson *et al.* (1946) also noticed a much higher concentration in liver than in either type of muscle studied.

Vitamin B_6. According to Cheldelin and Williams (1942) the concentration of vitamin B_6 is higher in breast of chicken than in leg.

Biotin. Cheldelin and Williams (1942) and Cheldelin *et al.* (1943) found leg muscle of chicken richer than breast, but Schweigert, Nielsen, McIntire and Elvehjem (1943) found no great difference between the concentrations in dark and light meat. Their value for light meat was slightly greater than for dark meat.

Folic acid. Cheldelin and Williams (1942) and Cheldelin *et al.* (1943) found no marked difference in folic acid concentration between leg and breast muscle of the chicken and Toepfer *et al.* (1951) no appreciable difference between light and dark meat, but the values obtained by each of these groups of workers for breast or light meat tended to be slightly higher than the corresponding values for leg or dark meat. The results of Moore, Lepp, Luckey, Elvehjem and Hart (1947) and Toepfer *et al.* (1951) indicate that liver is much richer than muscle.

Vitamin B_{12}. According to Elvehjem (1950) the concentrations in the dry matter of chicken leg and breast are much the same.

Vitamin B complex in general. From the above evidence it appears that liver of the chicken and turkey, although usually richer in vitamin B_1 than gizzard and skin, is occasionally poorer than heart and some of the skeletal muscles. The concentration of riboflavin is higher in liver than in skeletal muscle, but the concentration of nicotinic acid is usually about the same in liver and breast muscle. Dark muscles of both species are richer in vitamin B_1 and riboflavin, but poorer in nicotinic acid, than light muscles. Evidence about other B vitamins is meagre, but it appears that liver of chicken is much richer in pantothenic acid than heart, gizzard, skin or skeletal muscle, and that dark muscles are richer in it than light muscles.

Vitamin C. Bessey and King (1933) found that the adrenal glands of the chicken are much richer in vitamin C than the brain, liver, testes, kidney or heart. The liver, though poorer than the adrenal glands and brain, was richer than the other organs studied and was much richer than the muscles. Giroud *et al.* (1938) analysed the adrenal glands, liver and kidneys of eight species of bird, including the chicken, duck, goose and partridge. The adrenal glands were in all instances much richer in vitamin C than the liver, and the liver, in all species except the goose, was richer than the kidneys.

Vitamin D. The vitamin is present in chicken liver (see, *e.g.*, Daniel and Munsell, 1937 ; Waisman and Elvehjem, 1941).

Vitamin E. Criddle and Morgan (1951) reported that tocopherols are widely distributed in the tissues of the turkey, and that the concentration is higher in liver and heart than in gizzard or skeletal muscle, and in leg muscle than in breast. The addition of tocopherol to the diet increased the concentrations in liver, heart, gizzard and muscle, but the total amount of the supplement retained was extremely small.

Fish and Shellfish

Little attention has been paid in recent years to the distribution of vitamins in the tissues of fish and present knowledge is for the most part based on investigations made before 1940. Nothing appears to be known about the distribution within the muscular tissues.

Vitamin A. It has long been known that the livers of many species of fish are rich in vitamin A and much information has accumulated on the relative concentrations in different species (see, *e.g.*, Daniel and Munsell, 1937 ; Fixsen and Roscoe, 1939–40). It was not at first realised, however, that the livers of some species contain, in addition to vitamin A itself, a biologically active compound of similar chemical structure, to which Edisbury, Morton and Simpkins (1937) gave the name vitamin A_2. Moreover, the detailed studies of Edisbury, Morton, Simpkins and Lovern (1938) on the distribution of vitamin A in the viscera of a number of species, including the herring, haddock, cod, halibut, turbot, salmon, trout and perch, showed that vitamin A is frequently concentrated in the walls of the intestinal tract as well as in the liver. The pyloric caeca were found to be particularly good sources of the vitamin and, although the stomach usually contained little or none, the intestines were moderately rich in it. In the conger eel half of the vitamin A was present in the liver and most of the remainder in the body fat and adipose tissue of the gonads.

Edisbury *et al.* (1938) further showed that the eyes of many vertebrate fish, including the haddock, hake, whiting, halibut and herring, contain vitamin A and that exceptionally high concentrations are present in the eyes of the goldfish. That the eyes of crustaceans contain vitamin A was demonstrated by Neilands (1947) for the American

lobster (*Homarus americanus*), and by Fisher, Kon and Thompson (1952) for different species, including the common lobster (*H. vulgaris*).

In the oyster a higher concentration of carotenoids in the visceral mass than in the mantle and gills was found by Brooks and Paulais (1939).

Few studies have been made of the distribution of vitamin A within individual tissues. Lovern and Morton (1939) examined the coats of the intestine of the halibut and found that vitamin A is sharply localised in the mucosa and in particular in the tunica propria layer of the mucosa. In an examination of fish liver by fluorescence microscopy, vitamin A fluorescence was seen in medium-sized fat droplets which fill the cytoplasm of the cells, but not in the Kupffer cells (see Popper, 1944). The distribution in fish liver differed from that in mammalian liver, the Kupffer cells of which show fluorescence.

Vitamin B_1. The results of Lunde *et al.* (1938) show that in a number of species of marine vertebrates, including the cod, flounder, haddock and mackerel, the concentration of vitamin B_1 is higher in hard roe than in liver. The same workers showed that the concentration is higher in hard than in soft roe of cod, and in liver than in muscle of cod, flounder, haddock and mackerel, but not herring.

Riboflavin. Lunde *et al.* (1938) found higher concentrations in hard roe than in liver of a number of species, including cod and ling but not flounder, and higher concentrations in hard than in soft roe of cod, and in liver than in muscle of cod and flounder. A higher concentration in the visceral mass than in the gills and mantle of the oyster was reported by Brooks and Paulais (1939).

Vitamin B_{12}. Of tissues from the sockeye salmon analysed by Tarr, Southcott and Ney (1950), the kidneys had much the highest concentration of vitamin B_{12}, expressed on a dry matter basis. The concentration in the liver was lower than in the spleen or pyloric caeca. In the ling cod the concentration was much higher in the dry matter of liver than of muscle.

Vitamin C. The investigations of Giroud *et al.* (1938) have shown that in several species of vertebrate fish the liver has a higher concentration of vitamin C than the muscles, and that in molluscs and crustaceans the hepato-pancreas is richer than the muscle. In the oyster a higher concentration in the visceral mass than in the gills and mantle was reported by Brooks and Paulais (1939). The results of Matsubara and Chuda (1937) show that the concentration of vitamin C is higher in the roe than in the liver or muscle of a number of species of fish inhabiting Japanese waters.

Vitamin D. It is well known that the body oils as well as the liver oils of fish are important sources of vitamin D (see, *e.g.*, Bills, 1935, for a summary of information and references). The concentration of vitamin D in the liver oil varies widely from one species to another and also between individual fish of the same species. In a given species the concentration in the liver oil tends to be inversely related to the yield of oil (see, *e.g.*, Hess, Bills and Honeywell, 1929). The amounts of body oil are relatively large in many species, but the concentrations of vitamin D are, in general, lower in body oils than in the corresponding liver oils. The muscles and the liver are the chief sites of fat deposition in fish, but the viscera and head also contain some oil. The milt and roe of cod and other species contain important amounts of vitamin D (Hess, Bills, Weinstock, Honeywell and Rivkin, 1928).

Eggs

Vitamin A. It was shown by Munsell as early as 1924 that the vitamin A activity of the hen's egg is confined to the yolk. Little attention has been paid to the question in later years.

Vitamin B_1. There is much evidence to show that vitamin B_1 is almost but not entirely confined to the yolk (Chick and Roscoe, 1929; Baker and Wright, 1935; Bethke, Record and Wilder, 1936; Booher and Hartzler, 1939; French, Abbott and Townsend, 1951).

Riboflavin. It was shown by Chick and Roscoe (1929) and Bethke *et al.* (1936) that riboflavin is present in both yolk and white of eggs. More recent investigation has shown that the concentration is usually but not invariably higher in the yolk than in the white of fresh eggs (see, *e.g.*, Norris and Bauernfeind, 1940; Stamberg, Petersen and Lampman, 1946*a*; French *et al.*, 1951; Evans, Butts and Davidson, 1952). The investigations of Stamberg *et al.* (1946*b*) showed that out of 279 eggs from farm flocks consisting of 4 common breeds of hens, 74 per cent. of the eggs had a higher concentration of riboflavin in the yolk than in the white; on the average, the concentration in the yolk was 1·22 times that in the white. Adrian (1952) also found a higher average concentration in the yolk than in the white of eggs from Rhode Island Red hens kept under controlled conditions, but equal concentrations in the yolk and white of commercial eggs.

Nicotinic acid. Available evidence shows that nicotinic acid is present in both the yolk and the white of fresh eggs and that the concentration is higher in the white than in the yolk (Teply *et al.*, 1942; Charkey, Dyar and Wilgus, 1947; French *et al.*, 1951; Evans, Butts and Davidson, 1951*a*; Adrian, 1952).

Pantothenic acid. Several investigators have shown that the concentration of pantothenic acid is much higher in the yolk than in the white of

fresh eggs (Jukes, 1941 ; Snell, Aline, Couch and Pearson, 1941 ; Evans, Davidson and Butts, 1952 ; Adrian, 1952).

Vitamin B_6. Charkey *et al.* (1947) found that the concentration of vitamin B_6 was higher in the yolk than in the white of fresh eggs, but, in the microbiological method of analysis used, the test organism did not respond equally to pyridoxal, pyridoxamine and pyridoxine. Evans *et al.* (1951*b*) used a method which gave equivalent responses to the three forms of vitamin B_6 and they too found a higher concentration of total vitamin B_6 activity in the yolk than in the white. Rabinowitz and Snell (1948) estimated the three forms of vitamin B_6 separately in fresh eggs and found much higher concentrations of pyridoxal, pyridoxamine and total vitamin B_6 in the yolk than in the white. The concentration of pyridoxine was very low in both yolk and white, the value being higher, on the average, for the latter than for the former.

Biotin. Recent evidence shows that the concentration of biotin is much higher in the yolk than in the white of both fresh and stored eggs (Evans *et al.*, 1953*a*).

Folic acid. A much higher concentration of folic acid in egg yolk than in egg white has been reported by Charkey *et al.* (1947) and by Evans *et al.* (1953*b*), but neither group of workers used a preparation from pig or chick pancreas for the liberation of bound folic acid, and it is possible that the vitamin may not have been completely extracted. Toepfer *et al.* (1951), however, used a chick pancreas preparation and they also found yolk richer than white.

Vitamin B_{12}. According to Yacowitz, Miller, Norris and Heuser (1952) almost all the vitamin B_{12} in the egg is present in the yolk.

Vitamin C. Neither yolk nor white of the fresh egg contains vitamin C (Hauge and Carrick, 1925 ; Ray, 1934 ; Satterfield, Bell, Cook and Holmes, 1947).

Vitamin D. As early as 1923 it was demonstrated that egg yolk has pronounced antirachitic properties and that egg white is devoid of activity, thus indicating that vitamin D is confined to the yolk (Hess, 1923).

Vitamin E. Small amounts of vitamin E are present in eggs (see, *e.g.*, Barnum, 1935, for biological results, and Harris *et al.*, 1950, for chemical

TABLE 7

AVERAGE CONCENTRATION OF B VITAMINS IN THE YOLK AND WHITE OF FRESH EGGS PRODUCED BY HENS ON NORMAL LAYING RATIONS

Vitamin	No. of eggs analysed	Breed of hen	Average concentration of vitamin in egg: yolk (mg. per 100 g.)	Average concentration of vitamin in egg: white (mg. per 100 g.)	Authority
Vitamin B_1	not stated	New Hampshire	0·234	0·002	French *et al.* (1951)
	,,	White Leghorn	0·286	0·002	
Riboflavin	156	White Leghorn	0·471	0·384	Stamberg *et al.* (1946*b*)
	24	Rhode Island Red	0·410	0·474	
	54	New Hampshire	0·492	0·388	
	45	Barred Plymouth Rock	0·420	0·299	
	24	White Leghorn	0·415*	0·314*	Evans, Butts and Davidson (1952)
Nicotinic acid	24	White Leghorn	0·016 *	0·093 *	Evans *et al.* (1951*a*)
Total vitamin B_6 (as pyridoxine)	30	White Leghorn	0·308	0·217	Evans *et al.* (1951*b*)
Pantothenic acid	24	White Leghorn	3·06 *	0·304 *	Evans, Davidson and Butts (1952)
Biotin	30	White Leghorn	0·052 *	0·007 *	Evans *et al.* (1953*a*)
Folic acid	30	White Leghorn	0·0232	0·0016	Evans *et al.* (1953*b*)

* Eggs boiled before analysis.

results). It is probable that, being fat-soluble, tocopherols are confined to the yolk (*cf.* vitamins A and D in eggs), but there appears to be no clear evidence on the point.

Vitamin distribution in albumin. Charkey *et al.* (1947) analysed separately two different fractions of the albumin of fresh eggs, namely, the firm albumin and the combined inner and outer fluid albumin. Their results showed that the firm and fluid portions did not differ appreciably in their concentration of nicotinic acid, vitamin B_6 or folic acid.

Effect of cold storage on eggs. Evans and co-workers showed in a series of investigations that transference of B vitamins may take place from the portion of higher to that of lower concentration during prolonged storage of eggs at 0° C. There was a slight transference of nicotinic acid from white to yolk (Evans *et al.*, 1951*a*), and of riboflavin (Evans, Butts and Davidson, 1952), pantothenic acid (Evans, Davidson and Butts, 1952) and folic acid (Evans *et al.*, 1953*b*) from yolk to white, but no transfer of biotin between yolk and white even after storage for 12 months at 0° C. (Evans *et al.*, 1953*a*).

Discussion

In the preceding sections many aspects of vitamin distribution in animal products have been mentioned about which the information available is often too meagre to warrant further discussion at the present time. The discussion which follows has been limited to a few topics, about which a reasonably large amount of information is now available, and which have not been extensively reviewed elsewhere.

A discussion of metabolic factors which may influence vitamin distribution in organs such as the liver and the kidneys has not been included. For further information on that question there are reference works such as those of Williams, Eakin, Beerstecher and Shive (1950) and Sebrell and Harris (1954).

Distribution of Vitamins in Muscular Tissues

It is well known that the B vitamins present in animal tissues are derived for the most part at any rate from dietary supplies, which may be supplemented through biosynthesis by micro-organisms in the intestinal tract. Synthesis by the tissues cannot be entirely excluded, for it appears that the liver is able to synthesise nicotinic acid from tryptophan. There is much evidence to show that vitamin B_1, riboflavin, and nicotinic and pantothenic acids are required for many processes in carbohydrate metabolism including fat synthesis, but it seems probable that vitamin B_1 is not needed for the utilisation of pre-formed fat as a source of energy. Thus, a sparing effect of dietary fat on the vitamin B_1 requirement of the animal body has been reported. In the muscles those four B vitamins, although playing no part in muscle contraction itself, are required for the production from glucose of the high-energy phosphate bonds which form the immediate source of energy for muscular activity (see, *e.g.*, Williams *et al.*, 1950).

The fact that the dark meat of the chicken is constantly richer in vitamin B_1, riboflavin and pantothenic acid but poorer in nicotinic acid than the light meat is of particular interest because clear-cut histological and functional differences exist between the two types of striated muscle. The dark muscles of the leg, which consist of so-called red fibres, are muscles of posture required to remain contracted over long periods of time; the light-coloured breast muscles, on the other hand, are composed of white fibres and are required for rapid but intermittent use, as in flight (see Cowdry, 1938; Clark, 1945). It seems unlikely that the differences in B vitamin concentration between the two types of muscle can be attributed solely to differences in the amounts of fat and connective tissue present. It, therefore, seems probable that red and white muscle fibres differ consistently in B vitamin concentration in the chicken. There is a further suggestion that the amounts present in each particular sort of muscle cell may be related to the type of work performed.

Similar conclusions probably apply to the turkey. There appears to be no information about other species of birds, but it would be interesting to know if the breast muscles of flying birds such as the pigeon differ appreciably in B vitamin concentration from those of the chicken and turkey which rarely fly. Gruber and Ruys (1951) estimated thiamine pyrophosphate, which accounts for most of the vitamin B_1 activity of animal organs, in breast muscle, heart and liver of carrier pigeons immediately after a long flight and in similar resting birds, but they did not examine other muscles. No evidence was found in any of the tissues studied of a lower concentration of thiamine pyrophosphate in flying than in resting birds. It was calculated that over 80 per cent. of the energy needed for the flight must have come from sources other than glycogen and glucose, and in explanation of the findings it was suggested that fat, which, as stated previously, probably does not require vitamin B_1 for its utilisation, must have formed the main source of energy.

In the rabbit, as well as the chicken, a number of muscles consist entirely of either red or white fibres (see, *e.g.*, Clark, 1945). It is of interest to note that in the rabbit also muscles composed entirely of red fibres, such as the soleus, tend to be

richer in vitamin B_1 and riboflavin than muscles composed of white fibres. The distribution of nicotinic and pantothenic acids in the muscles of the rabbit has unfortunately not been determined.

In most other mammals red and white fibres are intermingled in the muscles. Red fibres tend to predominate in some muscles and white fibres in others, but the morphological and functional differences between individual muscles are much less clearly defined than in the rabbit and the chicken. Moreover, a particular muscle may vary in colour and function from one species to another (see Hammond and Appleton, 1932 ; Clark, 1945). It is therefore difficult in the ox and pig to judge to what extent the recorded differences in B vitamin concentration between individual muscles are related to the relative proportions of red and white fibres present or to the type of muscular work performed.

The finding of much higher concentrations of vitamin B_1 in the skeletal muscles of the pig than in those of other mammals suggests that factors other than muscular activity probably influence the amounts of B vitamins which accumulate in muscle cells. Pyke (1940) considered that, since vitamin B_1 is involved in the utilisation of glucose by cells, its concentration may be related to that of glycogen, and he produced some evidence of an inverse relation between the amounts of the two substances present in muscles. For pork muscle which is rich in vitamin B_1 Pyke cited evidence that the amount of glycogen present is low and is rapidly depleted by exercise. Heinemann *et al.* (1946) showed that the amount of vitamin B_1 in pork muscle is much increased when the diet is rich in vitamin B_1, and is reduced when the diet is deficient, and they concluded that the muscles of the pig are an important storage depot for the vitamin.

It would be of interest to know whether or not the wild pig, which is both leaner and more active than the domestic pig, is capable of storing vitamin B_1 in its muscles in a similar way, but there appears to be no information on the point. There is evidence that vitamin B_1 is required for fat synthesis (see, *e.g.*, Williams *et al.*, 1950) ; fat deposition is greatly reduced in vitamin B_1 deficiency in the pig (Heinemann *et al.*, 1946). Since, however, the latter effect may be due merely to reduced feed intake, and since other B vitamins, which do not accumulate to any great degree in pork muscle, are required also for lipid synthesis, a relation between muscle storage of vitamin B_1 and lipogenesis seems improbable in the pig on the basis of the present evidence.

The fact that the concentration of vitamin B_1 is much higher in heart than in skeletal muscle of a number of species suggests that individual fibres in the two kinds of muscle may contain very different amounts of the vitamin and, further, that the differences may to some extent be associated with the type of work performed. The finding of a higher concentration of vitamin B_1 in the ventricles than in the auricles of the heart is also of interest, for the former do more work than the latter. The possibility cannot be excluded, however, that this difference in vitamin B_1 concentration may arise merely through the presence of more connective tissue and, consequently, of relatively less muscular tissue in the auricular than in the ventricular wall (see, *e.g.*, Maximow and Bloom, 1948).

Distribution of Vitamins in the Egg

In considering the distribution of vitamins between the yolk and the white, account must be taken of the fact that these two portions of the egg are laid down at different times and in different parts of the reproductive tract of the hen (see, *e.g.*, Sturkie, 1954), and that they differ in basic composition, the former containing more fat but less water than the latter (see Needham, 1931).

Available evidence shows that the fat-soluble vitamins are deposited in the yolk with most of the lipids, and remain exclusively in that part. With some of the water-soluble vitamins also, namely vitamin B_1, pantothenic acid, folic acid and biotin, deposition apparently takes place mainly in the yolk, and subsequent equilibration by diffusion from yolk to white does not occur to any great extent in spite of the fact that the vitelline membrane is permeable to water (see Needham, 1931 ; 1942). On the basis of the present evidence it cannot be definitely decided whether or not equilibration plays a part in the distribution of riboflavin, nicotinic acid and vitamin B_6 between yolk and white in the fresh egg. The slight tendency in stored eggs towards equilibration of riboflavin and nicotinic, pantothenic and folic acids may be associated with degenerative changes in the vitelline membrane. The movement of water from white to yolk which takes place during cold storage (Evans and Davidson, 1951) may assist the passage of nicotinic acid from white to yolk, but would, if anything, impede the movement of those B vitamins which migrate in the opposite direction.

It is probable that many of the B vitamins in the egg are present, at least in part, in a bound form which is not readily diffusible. Thus, György and Rose (1942) showed that egg yolk contains an undialysable but biologically active bound form of biotin. The finding is of particular interest in view of the fact that avidin, the anti-biotin factor which binds biotin in a form unavailable to animals, is present in egg white (see, *e.g.*, Eakin, Snell and Williams, 1941, for references).

There is evidence that the greater part of the protein of egg white is deposited in the portion of the hen's oviduct known as the magnum (see Sturkie, 1954, for references). Whether the B vitamins of egg albumin are laid down with the protein, or whether they are added later in the uterus with the water and salts which diffuse in through the shell and shell membrane at that stage, has not yet been definitely established. The uterine fluid contains very little nitrogenous matter (Beadle, Conrad and Scott, 1938) and it seems unlikely that diffusion through the shell is the chief mode of entry of the B vitamins. Bolton (1952) has recently produced evidence that riboflavin is deposited while the egg is in the magnum. Fraps, Hertz and Sebrell (1943) have shown that avidin is present in the magnum of the laying hen and not in the lower portions of the reproductive tract.

Though the thin and the thick albumin of the laid egg differ in viscosity, they contain similar proportions of water (Holst and Almquist, 1931 ; Charkey *et al.*, 1947). The fact that they do not differ in B vitamin concentration suggests that equilibration takes place during the period in which the egg is in the uterus, or after it has been laid.

It is well known that the yolk supplies much of the food material required by the growing embryo, but evidence is available also that the white is utilised (see Needham, 1931 ; 1942). Whether or not the distribution of vitamins between yolk and white has a special significance in the embryological development of the chick is not as yet clear. Information about the distribution of vitamins within the egg at different stages during incubation would be of interest in this connection, but is at present almost entirely lacking. There is evidence that vitamin C although absent from the fresh egg is present in the embryo soon after incubation begins (Ray, 1934).

SUMMARY

Available information is summarised on the distribution of vitamins in the tissues of each of a wide range of foodstuffs. There is evidence in many foods of an uneven distribution of vitamins between the constituent tissues, the vitamins in some cases being confined almost entirely to one particular tissue.

In cereal grains vitamin B_1 is concentrated in two very narrow regions, the scutellum portion of the germ and the aleurone layer, and nicotinic acid is largely confined to the aleurone layer.

In many fruits vitamin C is present in a higher concentration in the outer skin or peel than in the inner tissues, but the proportion of the total vitamin C of the fruit which is contained in the outer tissues is not necessarily high in thin-skinned fruits.

In leafy vegetables the concentrations of carotene and vitamin C are usually higher in the leaves than in the stalks, and that of carotene is higher in the outer than in the inner leaves. In subterranean parts of plants, such as parsnip roots or potato tubers, the concentration of vitamin C tends to be higher in the interior than at the periphery.

Among animal tissues liver and kidney are conspicuously rich in vitamins and skeletal muscles are as a rule relatively poor. The muscles of the pig are exceptionally rich in vitamin B_1.

In many species of animals there are consistent differences between individual skeletal muscles, but it has been found that corresponding muscles from opposite sides of the same carcase have similar concentrations of B vitamins.

In the chicken and the turkey the dark muscles are richer in vitamin B_1 and riboflavin but poorer in nicotinic acid than the light muscles, and in the rabbit the red muscles are richer in vitamin B_1 and riboflavin than the white muscles. In the pig, muscles rich in vitamin B_1 tend to be rich also in nicotinic acid and poor in riboflavin and pantothenic acid.

The lumbar part of the longissimus dorsi muscle in pork loin is slightly richer in vitamin B_1 than the thoracic part, and the ventricular wall of beef and pork heart is slightly richer than the auricular wall.

The vitamins A, B_1, and D of the hen's egg are confined almost entirely to the yolk. A number of other B vitamins are present in both the yolk and the white, but with most of them the concentration is higher in the former than in the latter. The concentration of nicotinic acid is consistently higher in the white than in the yolk.

A number of morphological, biochemical and physiological conditions which may influence vitamin distribution in plant and animal tissues, and some practical applications of the findings recorded in this review, are enumerated and briefly discussed.

ANALYTICAL METHODS

General

1372

MERRILL, A. L. and WATT, B. K. **Energy value of foods—basis and derivation.** *U.S. Dept. Agric., Agric. Handbook* No. 74; March 1955, pp. 105.

In the United States Department of Agriculture Handbooks Nos. 8 and 34 (Absts. 4782, Vol. 20; 1686, Vol. 22) the system of calculation of energy from protein, carbohydrate and fat contents involved the use of factors, more specific than 4, 4 and 9, which " have been developed along the lines of Atwater's plan but take into consideration the more recent literature on digestibility and physiological energy value of foods ". These newer data have been summarised and are presented in a massive table running to 40 pages of this Handbook. In the text there is an interesting analysis of Atwater's book, which was completed 50 years ago, and a reproduction of some of his original data. From it all a table is derived of the factors which, on the basis of the experimental work now available, are thought suitable for the calculation of the energy available to the body from 47 individual foods or types of foodstuff.

STREULI, H. Elution farbiger Flecken von Papierchromatogrammen. [**Elution of coloured spots from chromatograms on paper.**] *Mitt. Geb. Lebensmittel. Hyg.*, 1955, **46**, 340. [Zürich.] French and English summaries.

The technique described is designed to use a minimum volume of eluting solvent. A square of the developed chromatogram containing the spot is cut out and again developed by ascending chromatography with a solvent in which the compound to be eluted has an R_F value of unity. For this purpose a beaker containing glass beads almost covered with solvent is used, the beads serving to support the paper vertically. After the second development the uppermost horizontal strip of the paper, containing the desired compound, is cut off, wedged by means of a glass-wool plug in the stem of a glass funnel and eluted by the addition of small amounts of solvent.

1377

BUSSARD, A. and PERRIN, D. **Electrophoresis in agar plates.** *J. Lab. Clin. Med.*, 1955, **46,** 689–701. [Inst. Pasteur, Paris.]

The agar is supported on glass plates and connected to electrodes by gauze pads impregnated with agar. Evaporation is prevented by covering the plates with a layer of plastic. Agar solutions containing the substances being examined are placed in holes in the plate and allowed to gel before electrophoresis. After the run the plastic layer is removed and the plates are printed on filter paper, which is then sprayed with appropriate detecting reagents. Alternatively, for proteins, the plate may be stained directly. After staining, the plates may be dried and scanned photometrically. Tailing of proteins does not occur.

GARCIA-BLANCO, J. and PASCUAL-LEONE, A. M. La reducción del ácido crómico en solución sulfúrica por los diversos aminoácidos naturales. [**Reduction of chromic acid in solution in sulphuric acid by natural amino-acids.**] *Rev. española Fisiol.*, 1955, **11**, 143–147. [Lab. Fisiol. Gen., Fac. Med., Valencia.] English summary.

The amino-acids were dissolved in water or HCl solution. The test solution was prepared by slow addition of 1 ml. 0·5 *N* or 0·25 *N* potassium chromate to 20 ml. concentrated H_2SO_4, and 1 ml. of this was added immediately to 1 ml. amino-acid solution, in a boiling-water bath. The reduction of yellow chromate to blue-green indicates the end-point of the reaction. The smallest amount of amino-acid capable of reducing the potassium chromate in 10 min. was found.

The concentrations of amino-acid necessary, in mg. per ml., were *iso*leucine 0·125, leucine, tyrosine, lysine and serine 0·185, arginine 0·25, cystine, cysteine and valine 0·375, phenylalanine and methionine 0·5, histidine 1, proline 2, aspartic and glutamic acids 60, alanine 100 and glycine 200.

D. Duncan.

GARCIA-BLANCO, J. and PASCUAL-LEONE, A. M. Diferenciación de algunos aminoácidos naturales por su capacidad reductora del ácido vanádico a sal de vanadilo. [**Differentiation of some natural amino-acids by their capacity to reduce vanadic acid to a vanadyl salt.**] *Rev. española Fisiol.*, 1955, **11**, 149–152. [Lab. Fisiol. Gen., Fac. Med., Valencia.] English summary.

The reagent consisted of 10 mg. ammonium vanadate mixed with 1 ml. water and then 9 ml. concentrated sulphuric acid, added slowly. To 1 ml. amino-acid solution was added 1 ml. reagent. A positive reaction is characterised by change of colour from orange to blue.

The amino-acids which gave positive reactions, and the amounts in mg. necessary to reduce 1 mg. vanadate, were cysteine 0·25 to 0·125, cystine 0·5 to 0·25, methionine 0·5 to 0·25 and tyrosine [" thyroxine " in the English summary must be an error] 4 mg. Tryptophan, 0·125 mg., gave an intense dark brown colour. No reaction was given by glycine, alanine, serine, valine, leucine, *iso*-leucine, phenylalanine, lysine, arginine, aspartic acid, glutamic acid or histidine.—D. Duncan.

1415

GERLAXHE, S. and CASIMIR, J. Note concernant la séparation des acides ω aminés par chromatographie sur papier en présence de tampon. [**Note on the separation of ω-amino-acids by paper chromatography in the presence of a buffer.**] *Bull. Inst. agronom. Gembloux*, 1955, **23**, 352–354. [Lab. Chem. Gén., Centre Nat. Chim. Org.]

β-Alanine, γ-aminobutyric acid, δ-aminovaleric acid and ϵ-aminocaproic acid were separated by paper chromatography using butanol saturated with buffer as the solvent. Four buffers were tried and *p*H seemed to have little effect on the R_F values. A boric acid-NaOH buffer at *p*H 8·5 gave the best separation.—A. Hepburn.

[**Estimation of amino-acids in biological material. 1. Principles of separation of ninhydrin-positive substances by column chromatography.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10**, 223–228. [Inst. Anat. Haustiere, Univ. Bonn.]

1417

PIEZ, K. A. and EAGLE, H. **Systematic effect of C^{14} labeling on ion-exchange chromatography of amino acids.** *Science*, 1955, **122**, 968–969. [Nat. Inst. Dent. Res., Bethesda, Md.]

It was shown that the presence of ^{14}C in a molecule of an amino-acid reduces its rate of movement on a Dowex-50 column, so that some resolution of labelled and unlabelled acid occurs during chromatography. The practical significance of this observation is discussed.—H. G. Bray.

1418

SCHNEIDER, F., REINEFELD, E. and MÜLLER, H. Zur schnellen quantitativen Bestimmung von

Aminosäuren, insbesondere von Glutaminsäure. [**Rapid quantitative estimation of amino-acids, especially glutamic acid.**] *Biochem. Ztschr.*, 1955, **327,** 189–194. [Inst. Landwirtsch. Technol., Tech. Hochsch., Brunswick.]

An electrophoretic method is described. The separation is performed at *p*H 3·7, the separated acids are stained with ninhydrin and the colours are measured photometrically. Glutamic, aspartic and α-aminobutyric acids alone or in beet molasses may be estimated with an error which is usually less than 4 per cent.—H. G. Bray.

1419

ROCHE, J., MICHEL, R. and NUÑEZ, J. Séparation chromatographique de divers acides aminés iodés au moyen de solvants volatils tamponnés. Application au constituants iodés du corps thyroïde. [**Chromatographic separation of some iodinated amino-acids by buffered volatile solvents. Application to iodinated constituents of the thyroid.**] *Bull. Soc. Chim. biol.*, 1955, **37,** 809–817. [Lab. Biochim. Gén., Coll. de France, Paris.]

1420

KHAN, N. A., BAKER, B. E. and VAN HORN, W. F. **Paper chromatography in routine determination of glutamic acid in production.** *J. Agric. Food Chem.*, 1955, **3,** 853–855. [Macdonald Coll., Quebec.]

Buffered filter paper, *p*H 12, is used, and the solvent is phenol saturated with the same buffer and containing 5 per cent. 2-butanol. Spots of the solution being analysed are run alongside standards and after development are detected by means of ninhydrin and estimated densitometrically. It is concluded that 8 replicate estimations are needed to give a reasonably reliable value for the glutamic acid content of a sample.—H. G. Bray.

1421

SELIM, A. S. M., EL-WAHAB, M. E. A. and EL-SADR, M. M. **A new method for the direct isolation of glycine from protein hydrolysates.** *Biochem. J.*, 1955, **61,** 177–179. [Dept. Biochem., Abbassia Fac. Med., Cairo.]

A sulphuric acid (8*N*) hydrolysate of gelatine is neutralised with $Ca(OH)_2$ and sulphate ions are removed with baryta and calcium ions with oxalic acid. The filtrate is concentrated *in vacuo* and treated with copper picrate and the glycine-copper picrate which crystallises is separated. Glycine is isolated from this by treatment with H_2SO_4, picric acid being extracted with benzene and Cu precipitated by H_2S. The filtrate is freed from H_2SO_4 with baryta and concentrated and glycine is precipitated by ethanol.—H. G. Bray.

1422

SCHWARTZ, T. B., ROBERTSON, M. C. and HOLMES, L. B. **A microdiffusion method for the determination of plasma glycine.** *J. Lab. Clin. Med.*, 1955, **46,** 657–661. [Med. Serv., Veterans Admin. Hosp., Duke Univ., Durham, N.C.]

Plasma, 1 ml., is diluted with 4 ml. picric acid solution and centrifuged and the glycine content of the supernatant fluid is estimated in a Conway unit. The liquid is evaporated to dryness and ethyl phosphate and ninhydrin are added. The formaldehyde formed diffuses into a chromotropic acid reagent and the colour produced is measured spectrophotometrically.—H. G. Bray.

1423

HUNTER, A. **A method of histidine determination based upon a modified Knoop reaction. 2.** *J. Biol. Chem.*, 1955, **216,** 391–394. [Res. Inst., Hosp. Sick Child., Toronto.]

The colorimetric estimation of histidine (see Abst. 1519, Vol. 22) was shown to be affected by the concentration of Br^- and the temperature at which colour developed. The method was modified by adding KBr to the bromine solution in tertiary butanol and keeping the temperature at 25° C. until the colour was fully developed. The best results were obtained with solutions containing from 0·12 to 0·28 mg. histidine per 5 ml.

A. Hepburn.

1424

COWGILL, R. W. **Colorimetric method for analysis of histidine and certain related imidazole compounds.** *Anal. Chem.*, 1955, **27,** 1521–1523. [Dept. Biochem., Univ. California, Berkeley.]

The method depends on the reaction of *p*-nitrobenzoyl chloride in acetone solution with imidazole derivatives to give derivatives of 1 : 2-di(*p*-nitrobenzamido)-ethylene. Interference by bases and phenols is not serious unless they are present in relatively large amounts. The method is applicable to as little as 4 μg. histidine if a spectrophotometer is used for the estimation.—H. G. Bray.

1425

PASIEKA, A. E. and MORGAN, J. F. **The detection of homocysteine in biological systems.** *Biochim. biophys. Acta*, 1955, **18,** 236–240. [Lab. Hyg., Dept. Nat. Health Welfare, Ottawa.] French and German summaries.

Homocysteine gave a cherry-red spot surrounded by deep blue on paper chromatograms sprayed with ninhydrin and then treated with mercuric nitrate. Inorganic salts, including chloride, phosphate and bicarbonate, catalysed the reaction. Nearly 80 other compounds, including homocysteine thiolactone and homocystine, failed to give this reaction.—A. Hepburn.

1426

BLACKBURN, S. and LEE, G. R. **The determination of lanthionine in amino-acid mixtures: the separation of its diastereoisomers on columns of ion-exchange resin.** *Analyst*, 1955, **80**, 875–879. [Wool Indust. Res. Assoc., Torridon, Headingley, Leeds 6.]

Lanthionine is isolated from protein hydrolysates or amino-acid mixtures by chromatography on Dowex-50, from which it is eluted between serine and glutamic acid. This procedure separates L- and *meso*lanthionine. A method is described for the colorimetric estimation of lanthionine by means of ninhydrin in acid solution; under the conditions described most common amino-acids give no reaction, proline and lysine being exceptions.—H. G. Bray.

1427

ROSENTHAL, H. L. **Determination of urea in blood and urine with diacetyl monoxime.** *Anal. Chem.*, 1955, **27**, 1980–1982. [Clin. Pathol. Labs., Div. Biochem., Rochester Gen. Hosp., N.Y.]

Lipoid Constituents

1428

CROCKER, W. P., JENKINS, D. I., PROVAN, A. L., MACDONALD, F. J., ROWLAND, S. J. and WHITE, J. C. D. **A comparison of the Gerber and Röse Gottlieb methods for the determination of fat in milk.** *J. Dairy Res.*, 1955, **22**, 336–339. [The Nestlé Co., Ltd., Hayes, Middlesex.]

The fat percentage in 208 samples of milk with a range of 2·5 to 6·0 per cent. obtained by the Gerber method (G) and the Röse Gottlieb method (RG) satisfied the equation $G = 1{\cdot}036\,RG - 0{\cdot}097$ (*cf.* Abst. 3058, Vol. 21). It is suggested that if the capacity of the Gerber milk pipette were reduced from 11·04 to 10·94 ml. the methods would agree for milks with a fat content of 3·6 per cent. and over the normal range of fat content there would be only a difference negligible for most purposes. Tables are given from which a correction can be applied if desired.—A. Hepburn.

1429

BOTTINI, E. and CAMPANELLO, F. L'olio idrogenato di delfinidi svelato nei burri per mezzo della cromatografia su carta. [**Detection of hydrogenated dolphin oil in butters by means of paper chromatography.**] *Ann. Sper. agrar.*, 1955, **9**, 11–20. [Staz. Chim. Agrar. Sper., Turin.] English summary.

Dolphin oil contains much *iso*valeric acid, 7·8 per cent. in the sample tested, and less butyric acid than butter. *iso*Valeric acid could be detected by paper chromatography when the butter contained as little as 3 per cent. hydrogenated dolphin oil.—D. Duncan.

1430

WUNDERLY, C. and WIEME, R. J. A propos du dosage des lipoïdes après électrophorèse sur papier. [**Estimation of lipids after electrophoresis on paper.**] *Arch. internat. Physiol.*, 1955, **63**, 318 – 327. [Med. Klin., Univ. Zürich.]

A critical study of the use of Sudan black and oil red to stain lipids separated by paper electrophoresis.—H. G. Bray.

1431

KIBRICK, A. C. and SKUPP, S. J. **Estimation of lipid fractions of blood plasma: system using the Allen volumetric method.** *Clin. Chem.*, 1955, **1**, 317–323. [Clin. Labs., Veterans Admin. Hosp., New York.]

The Allen method (*Proc. Soc. Exp. Biol. Med.*, 1934, **31**, 991), which depends finally on the measurement of a column of fat in a capillary tube, is calibrated for the recovery of known amounts of fat rather than by means of mercury. A procedure is described for the estimation of phospholipins, cholesterol and cholesterol esters, neutral fat, total lipids and total fatty acids.—H. G. Bray.

1432

JENCKS, W. P. and DURRUM, E. L. (with JETTON, M. R.) **Paper electrophoresis as a quantitative method: the staining of serum lipoproteins.** *J. Clin. Invest.*, 1955, **34**, 1437–1448. [Dept. Pharmacol., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

The separated lipoprotein is stained with oil red O or Sudan black and the adsorbed dye is eluted and estimated spectrophotometrically. The composition of the stains used and the solubility of the stained lipid in staining solvents are discussed.—H. G. Bray.

1433

PERILÄ, O. **Separation of saturated straight chain fatty acids. 2. Qualitative paper ionophoresis.** *Acta chem. scand.*, 1955, **9**, 1231–1232. [Finland Inst. Technol., Helsinki.]

For part 1 see Abst. 62, Vol. 26.

Acids from acetic to pelargonic can be separated ionophoretically at 25° C. by aqueous NaOH buffered with boric acid at *p*H 9, using a potential of 5 volts per cm. Acids from acetic to palmitic can be separated by means of 0·2 *N* NaOH in glycerol at 90° C.; this procedure is most suitable

for acids above caproic. Lower acids are detected with methyl red and those from valeric with rhodamine B.—H. G. Bray.

1434

WAGNER, H., ABISCH, L. and BERNHARD, K. Zur papierchromatographischen Analyse von Fettsäuregemischen aus gesättigten und ungesättigten Fettsäuren mit 12 bis 22 C-Atomen. **[Paper chromatographic analyses of fatty acid mixtures of saturated and unsaturated fatty acids with 12 to 22 C atoms.]** *Helv. chim. Acta*, 1955, **38**, 1536–1541. [Physiol. Chem. Inst., Univ. Basle.]

Paper impregnated with a petroleum fraction (b.p. 190° to 220° C.) is used, the developing solvent being a mixture of the same fraction with 90 per cent. acetic acid. After development the acids are converted to copper ferrocyanide complexes which can be estimated absorptiometrically on the paper.—H. G. Bray.

1435

VAN DE KAMER, J. H., PIKAAR, N. A., BOLSSENS-FRANKENA, A., COUVÉE-PLOEG, C. and VAN GINKEL, L. **Quantitative determination of the different higher saturated fatty acids in fat from blood, chyle and faeces, by means of partition chromatography on rubber.** *Biochem. J.*, 1955, **61**, 180–186. [Central Inst. Nutrit. Res. T.N.O., Utrecht.]

A column of rubber powder was used, with aqueous acetone of increasing concentration, from 30 to 80 per cent., as developing solvent. Unsaturated fatty acids are oxidised with alkaline permanganate before separation, since they interfere with the separation of saturated acids. This treatment attacks octanoic and decanoic acids and cannot be applied when they are present. Details of the extraction of fat from the materials studied vary and they are described separately. The method was applied to acids from C_6 to C_{22}.

H. G. Bray.

1436

HACK, M. H. **A method for the estimation of fatty acid esters.** *Arch. Biochem. Biophys.*, 1955, **58**, 19–23. [Dept. Med., Tulane Univ., New Orleans, La.]

Carboxylic esters were estimated colorimetrically from the lavender colour produced when the corresponding hydroxamic acid prepared by treatment with alkaline hydroxylamine reacted with ferric perchlorate. A list of esters which react includes fatty acid esters, cholesterol esters, vitamin A acetate, lecithin, cephalin, tributyrin and tristearin. Favourable recoveries were made of some of these substances alone or in binary mixtures.—A. Hepburn.

1437

RAPPORT, M. M. and ALONZO, N. **Photometric determination of fatty acid ester groups in phospholipides.** *J. Biol. Chem.*, 1955, **217**, 193–198. [Div. Labs. Res., New York State Dept. Health.]

1438

ALBERS, R. W. and LOWRY, O. H. **Fluorometric determination of 0·1 to 10 micrograms of cholesterol.** *Anal. Chem.*, 1955, **27**, 1829–1831. [Dept. Pharmacol., Sch. Med., Washington Univ., St. Louis, Mo.]

The method is based on the fluorescence given by cholesterol in the presence of sulphuric acid, acetic anhydride and trichloroethane, which develops in 5 to 10 min. and is stable for about 45 min. Samples of tissue containing from 0·1 to 2·0 μg. cholesterol are extracted with ethanol, the extract is treated with the reagents and the fluorescence is measured by comparison with standard solutions. No substance usually present in tissues interferes seriously with the method. Free and esterified cholesterol give nearly identical degrees of fluorescence.—H. G. Bray.

1439

MICHALEC, Č. **Paper chromatography of cholesterol and cholesterol esters.** *Naturwissenschaften*, 1955, **42**, 509–510. [Univ. Hosp., Prague.]

Ascending paper chromatography on Whatman No. 3 paper impregnated with a 10 per cent. solution of paraffin oil in benzene, with acetic acid as developing solvent, is used. Detection is by 10 per cent. phosphotungstic acid in ethanol or 50 per cent. antimony trichloride in acetic acid. R_F values are given for cholesterol and its acetate, caproate, palmitate, stearate and oleate.

H. G. Bray.

1440

LANGAN, T. A., DURRUM, E. L. and JENCKS, W. P. **Paper electrophoresis as a quantitative method: measurement of alpha and beta lipoprotein cholesterol.** *J. Clin. Invest.*, 1955, **34**, 1427–1436. [Dept. Pharmacol., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

After electrophoresis the paper strips are dried at room temperature. Some are sprayed with Sudan black to locate lipoprotein and segments corresponding to those which stain are cut from the others and eluted with a hot mixture of methanol and chloroform. Cholesterol is estimated in the eluates by means of a mixture of ferric chloride and H_2SO_4 (Abst. 3890, Vol. 23) or by the digitonin precipitation method of Schoenheimer and Sperry. Results obtained by the 2 methods are comparable.

H. G. Bray.

Other Organic Constituents

1441

BONTING, S. L. **Colorimetric determination of pyruvic acid and other α-keto acids in submicrogram quantities.** *Arch. Biochem. Biophys.*, 1955, **58,** 100–108. [Dept. Physiol., Coll. Med., State Univ. Iowa, Iowa City.]

From 0·1 to 1·0 μg. pyruvic acid or other keto-acid in a sample containing at least 2 μg. per ml. was estimated colorimetrically from the yellow colour of the hydrazone extract in Na_2CO_3 solution. Deproteinisation and the use of NaOH were unnecessary. Pyruvic acid could be differentiated from α-ketoglutaric acid or oxaloacetic acid by varying the reaction time and the organic solvent.

A. Hepburn.

1442

ADAMSON, L. F. and GREENBERG, D. M. **Separation of the acid precursors of cholesterol by column chromatography.** *Biochim. biophys. Acta*, 1955, **18,** 516–518. [Dept. Physiol. Chem., Sch. Med., Univ. California, Berkeley.]

By means of the silica gel column and eluting solvents described by Kinnory *et al.* (Abst. 3940, Vol. 25) the following proposed acid precursors of cholesterol were separated: ββ-dimethylacrylic acid, β-hydroxy*iso*valeric acid, β-hydroxy-β-methylglutaric acid, β-methylglutaconic acid and acetic acid. Separate titration peaks were obtained, with the benzene-ether solvent system, for all the acids except acetic and β-methylglutaconic acids, which were eluted together; these acids were resolved by the preliminary use of a 1 : 1 mixture of light petroleum and ether as developing solvent.

G. A. Garton.

1443

ENGLIS, D. T., BURNETT, B. B., SCHREIBER, R. A. and MILES, J. W. **Determination of benzoic and salicylic acids in food products.** *J. Agric. Food Chem.*, 1955, **3,** 964–969. [Dept. Chem., Univ. Illinois, Urbana.]

Benzoic and salicylic acids could be estimated, either alone or in mixtures, by ultraviolet spectrophotometric examination at selected wavelengths. Benzoate was estimated in ketchup, orange base concentrate and margarine.—A. Hepburn.

FAGEN, H. J., KOLEN, E. P. and HUSSONG, R. V. **Spectrophotometric method for determining piperine in oleoresins of black pepper.** *J. Agric. Food Chem.*, 1955, **3,** 860–862. [Kraft Foods Co. Res. Labs., Glenview, Ill.]

1446

FENWICK, M. L. and PARKER, V. H. **The determination of 3 : 5-dinitro-*o*-cresol in the presence of β-carotene in biological tissues.** *Analyst*, 1955, **80,** 774–776. [Fisons Pest Control, Ltd., Bourn, Cambridge.]

See also Abst. 1588.

Inorganic Constituents

1447

THOMPSON, A. and RAVEN, A. M. **Soil contamination of herbage samples.** *J. Sci. Food Agric.*, 1955, **6,** 768–777. [Sch. Agric., King's Coll., Univ. Durham.]

Italian ryegrass was grown in soil-less culture. Soil was added to the dried ground herbage to give a series of samples with up to 10 per cent. contamination. With the soil used (not calcareous), contamination had little effect on the silica-free ash, Ca and Na contents of the samples. K, Cl, Mg and P contents were reduced by 7 to 14 per cent., probably owing to dilution with soil. Cu showed a slight increase but with Fe and Co the increases were so great that soil contamination as low as 2 per cent. more than doubled the amount present in the soil-free grass. With Mn a similar error was obtained at the 10 per cent. contamination level.

Leaching effects from washing herbage were studied, though the efficacy of the treatments in removing contaminating soil was not investigated. Spraying with water for 3 min. caused little loss of ash constituents. A 5-min. soaking removed one-third of the silica and Co. Most constituents showed considerable losses after soaking for 1 hr.

Al content was found to provide a good measure of the degree of soil contamination in herbage. A method for its estimation is described.

J. L. Corbett.

1448

VANATTA, J. C. and LANDERS, R. M. (Jr.) **The determination of total base of urine with an ion exchange resin conditioned as iodate.** *J. Biol. Chem.*, 1955, **216,** 351–355. [Dept. Physiol., Univ. Texas Southwestern Med. Sch., Dallas.]

Urine was diluted and passed through a resin column. Total base was estimated from the amount of iodate liberated (see Abst. 4100, Vol. 24).

Total fixed base, taken as base content after ashing, could not be estimated directly in this way owing to the formation of insoluble Ca and Mg phosphates. Total fixed base estimated in 16 standard solutions after removal of phosphate by precipitation with ferric ammonium sulphate before ashing had errors of less than 2 per cent. Total fixed base plus ammonia differed on the average by 0·1 per cent. from total base concentration in the urines from 9 normal subjects and 6 patients in hospital.

1449

HAMM, R. Über die Bestimmung von Calcium, Magnesium, Zink und Eisen in tierischem Gewebe. [**Estimation of calcium, magnesium, zinc and iron in animal tissues.**] *Biochem. Ztschr.*, 1955, **327,** 149–162. [Chem. Physik. Inst., Bundesforschungsanst. Fleischwirtsch., Kulmbach.]

The material is ashed and the residue is dissolved in HCl. The solution is treated with a cation-exchange resin (Lewatit S 100) which adsorbs Ca, Mg and Zn, allowing phosphate and 90 to 95 per cent. of the Fe to pass through. Ca, Mg and Zn are eluted with HCl and estimated by titration with disodium ethylenediamenetetra-acetate. Fe is estimated spectrophotometrically with *o*-phenanthroline.—H. G. Bray.

1450

WILSON, A. A. **The determination of magnesium and calcium in serum or plasma with ethylenediaminetetra-acetic acid (EDTA).** *J. Comp. Pathol.*, 1955, **65,** 285–290. [Vet. Sci. Div., Res. Dept., Boots Pure Drug Co., Ltd., The Priory, Thurgarton, Notts.]

Ca is precipitated as its oxalate and Mg as magnesium ammonium phosphate. The precipitates are dissolved in 50 per cent. HNO_3 and the solutions are titrated with ethylenediamine tetra-acetic acid at 60° to 80° C. in the presence of KCN at *p*H 10, with solochrome black WDFA as indicator. In order to obtain a sharper end-point in the Ca titration the titrated Mg solution is added to the Ca solution before it is titrated.—H. G. Bray.

1451

DULCE, H. J. Flammenphotometrische Bestimmung von Ca und Mg im Harn. [**Estimation of calcium and magnesium in urine by flame photometer.**] *Hoppe-Seyler's Ztschr.*, 1955, **302,** 102–104. [Physiol. Chem. Inst., Freie Univ., Berlin.]

Ca in urine is precipitated as its oxalate and Mg as ammonium magnesium phosphate before flame photometry is applied.—H. G. Bray.

1452

HARRISON, H. E. and HARRISON, H. C. (with FLEISHMAN, E.) **A micromethod for determination of serum calcium.** *J. Lab. Clin. Med.*, 1955, **46,** 662–664. [Div. Paediat., Baltimore City Hosp., Md.]

In 0·2 ml. serum, Ca is precipitated as its oxalate, which is isolated by centrifuging. Excess ethylenediaminetetra-acetic acid is added and the excess is titrated against $CaCl_2$, with eriochrome black T as indicator.—H. G. Bray.

1453

THIERS, R. E., WILLIAMS, J. F. and YOE, J. H. **Separation and determination of millimicrogram amounts of cobalt.** *Anal. Chem.*, 1955, **27,** 1725–1731. [Pratt Trace Analysis Lab., Dept. Chem., Univ. Virginia, Charlottesville.]

The procedure described is applicable to biological material, *e.g.*, blood. The sample is dry-ashed and the ash is dissolved in HCl, some alkali chlorides and Fe are removed and the cobalt is separated by means of an ion-exchange resin (Dowex 1-X8) and spectrochemically estimated in the eluate.—H. G. Bray.

1454

SCHÜTTE, E. and KIESOW, L. Blausäurebildung als Fehlerquelle bei der Chloridbestimmung nach van Slyke. [**Hydrocyanic acid as source of error in chloride estimation by the Van Slyke method.**] *Hoppe-Seyler's Ztschr.*, 1955, **302,** 96–101. [Physiol. Chem. Inst., Freie Univ., Berlin.]

Hydrocyanic acid is formed from tyrosine and tryptophan during ashing of proteins with HNO_3. It is shown that an error of 60 per cent. is possible in the estimation of low chloride concentrations in protein preparations.—H. G. Bray.

1455

HERRMANN, R. Flammenspektrophotometrische Cu-Bestimmung im Serum. [**Estimation of copper in serum by flame spectrophotometry.**] *Ztschr. ges. exp. Med.*, 1955, **126,** 334–337. [Hautklin., Akad. Med. Forsch., Justus Liebig Hochsch., Giessen.]

Serum is deproteinised by adding HCl and trichloroacetic acid and removing the precipitate by centrifuging. The supernatant fluid is used directly for flame photometry.—H. G. Bray.

1456

ZAUSCH, G. Zur Methodik der Eisen- und Kupferbestimmung im Serum. [**Methods of estimating iron and copper in serum.**] *Klin. Wochenschr.*, 1955, **33,** 954–956. [Bakteriol. Chem. Inst., Städt. Behringkrankenhaus, Berlin-Zehlendorf.]

A study was made of the accuracy and sensitivity of the phenanthroline method for estimating iron, and of the carbamate method for estimating copper, in serum. For Fe, *p*H 2 gave the most satisfactory colour development and stability for comparison with standards for the reaction of the Fe-phenanthroline complex with α-dinitrophenol. In the estimation of Cu it was possible to avoid interference from Fe by using *iso*propanol as solvent and working above *p*H 8.—A. M. Copping.

1457

MOIR, K. W. **The preservation of bovine blood for the determination of inorganic phosphate in the diagnosis of aphosphorosis.** *Queensland J. Agric. Sci.*, 1954, **11,** 143–147. [Chem. Lab., Div. Plant Indust.]

The average increase of inorganic P in 18 blood samples stored at a final concentration of 1·5 per cent. trichloroacetic acid at 18° C. for 2 weeks was 0·14 mg. P with a maximum increase in 2 samples of 0·3 mg. P per 100 ml. On return to the laboratory 20 per cent. trichloroacetic acid and fuller's earth were added and the inorganic P was estimated colorimetrically after filtration.

A. Hepburn.

1464

LEWIS, P. R. **The micro-determination of potassium with dipicrylamine.** *Analyst*, 1955, **80,** 768–773. [Physiol. Lab., Cambridge.]

The procedure described is applicable to from 10 to 200 μg. potassium in biological materials. The sample is dry-ashed, the ash is dissolved in water and K is precipitated as its dipicrylamine salt under carefully controlled conditions. The

precipitate is separated by filtration on a filter-stick and dissolved in water, and its extinction is measured. Detailed instructions for making the filter-sticks are given. A procedure without filtration is also described. Interference by other elements which are likely to be present is small and the error in a single analysis is less than $\pm$ 2 per cent.—H. G. Bray.

1465

GLENDENING, B. L., PARRISH, D. B. and SCHRENK, W. G. **Spectrographic determination of rubidium in plant and animal tissues.** *Anal. Chem.*, 1955, **27,** 1554–1556. [Kansas State Coll., Manhattan.]

Interference by other elements may be reduced by the use of flame excitation and an instrument of high dispersion. Interference by K may be reduced by the use of a mask. Under the conditions described, as little as 1 p.p.m. rubidium can be estimated. Of the materials examined soya bean contained most Rb, from 160 to 225 p.p.m. dry weight. The content of other materials examined ranged from under 1 to 140 p.p.m.
H. G. Bray.

1466

RECHENBERGER, J. Zur Bestimmung des Serumzinks. [**Estimation of zinc in serum.**] *Ztschr. ges. inn. Med.*, 1955, **10,** 645–647. [Med. Klin., Univ. Leipzig.]

The micro-method is described in detail. It depends on splitting the Zn ions from the blood proteins with 6*N* HCl and 20 per cent. trichloroacetic acid, conversion of the Zn to Zn dithizonate, and colorimetric estimation of the red substance produced with filter S53.

The method was applied to the serum of 80 normal persons and gave a mean value for the Zn content of 145 μg. per cent. with range 115 to 185. No age or sex difference was found.—E. M. Hume.

Hydrogen Ion Concentration

1467

STANAGE, W. F., BROWN, J. M. and OBERST, B. B. **Colorimetric determination of blood plasma *p*H.** *J. Pediat.*, 1955, **47,** 571–575. [Child. Mem. Hosp., Omaha, Nebr.]

The principle that the colour change of an indicator varies with the *p*H was employed. The colorimetric examination of 3 standard buffers of known *p*H enabled a linear graph to be drawn relating optical density and *p*H. The optical densities at 38° C. of the unknown plasma plus a neutralised saline solution of phenol red under mineral oil and a control without indicator enabled the *p*H to be calculated. Accuracy ranged from 0·00 to 0·03 *p*H unit, average 0·014.—A. Hepburn.

Enzyme Activity

LUCHSINGER, W. W., CUENDET, L. S., BOYER, P. D. and GEDDES, W. F. **A sensitive method for measuring lipase activity and its application to wheat products.** *Cereal Chem.*, 1955, **32,** 395 – 404. [Dept. Agric. Biochem., Univ. Minnesota, St. Paul.]

The amount of glycerol released from a monoolein emulsion by lipase was used to measure the enzyme activity. After inactivation of lipase and destruction of the emulsion, glycerol in the aqueous phase was estimated by cleavage with periodate and measurement of the absorbance of the coloured complex of the resulting formaldehyde with added chromotropic acid. From 0·2 to 18·0 μg. glycerol could be estimated directly. Homogenates of the residues after extraction with light petroleum and ammonium sulphate solution were used to estimate lipase activity in wheat products.—A. Hepburn.

IVÁDY, J. and KOLTAY, M. Saggi semplici d'orientamento per la differenziazione del latte materno dal latte di vacca. [**Simple method of distinguishing between human and cow's milk.**] *Lattante*, 1955, **26**, 65–69. [Paediat. Klin., Univ. Szeged, Hungary.] English summary.

The method depends on the much greater degree of flocculation produced in cow's milk by certain reagents. Most satisfactory was an aqueous solution of 1·25 per cent. alum (*alumen ustum*) and 5 per cent. acetic acid. To 1 ml. human milk in a test tube 0·25 ml. of the reagent is added. If a small deposit appears on the sides of the tube and disappears again on addition of a further 0·5 or 1 ml. of the reagent, the milk is only slightly adulterated with cow's milk. If, however, the deposit increases, the milk contains more than 20 per cent. of cow's milk. Concentrated alcohol and 10 per cent. acetic acid can be used instead of alum.—E. M. Hume.

1477

BRIO, N. Opredelenie obshchego sukhogo ostatka v tzel'nom moloke. [**Estimation of total solids in whole milk.**] *Mol. Prom.*, 1955, **16**, No. 6, 26–27. [All-Union Inst. Milk Prod.]

The formula method of estimating the total solids in whole milk is the only one suitable for commercial work on a large scale, the analytical method being too lengthy. The formula is based on data on the density and fat content of milk. Several formulae are quoted, including Fleischman's, but none is said to be suitable for all districts.—H. Scherbatoff.

NUMEROF, P. **On the preparation of sodium chromate–Cr^{51} for red cell volume determinations.** *J. Lab. Clin. Med.*, 1955, **46,** 485–486. [Squibb Inst. Med. Res., New Brunswick, N.J.]

1488

EBAUGH, F. G., LEVINE, P. and EMERSON, C. P. **The amount of trapped plasma in the red cell mass of the hematocrit tube.** *J. Lab. Clin. Med.*, 1955, **46,** 409–415. [Robert Dawson Evans Mem. Lab., Massachusetts Mem. Hosps., Boston.]

The red cell concentrations of mixtures of 18 to 75 per cent. cells and plasma were estimated directly from haematocrit readings and indirectly by an isotope dilution technique, using haemoglobin labelled with ^{51}Cr. The difference between the 2 values was taken as the volume of plasma trapped in the red cell column. It was shown that there was a direct correlation between the length of the cell column and the amount of plasma trapped for haematocrit readings from 33 to 73 per cent. Below 33 per cent. no trapping of plasma could be detected.—H. G. Bray.

1489

TALSO, P. J., LAHR, T. N., SPAFFORD, N., FERENZI, G. and JACKSON, H. R. O. **A comparison of the volume of distribution of antipyrine, N-acetyl-4-amino-antipyrine, and I^{131}-labeled 4-iodo-antipyrine in human beings.** *J. Lab. Clin. Med.*, 1955, **46,** 619–623. [Dept. Med., Stritch Sch. Med., Loyola Univ., Chicago, Ill.]

The volume of distribution of 4-iodo-antipyrine labelled with ^{131}I was the same as that of antipyrine or N-acetyl-4-amino-antipyrine: 49·7, 50·6 and 50·6 per cent. of bodyweight, respectively.

H. G. Bray.

1490

KARPELES, L. M. and HUFF, R. L. **Blood volume of representative portions of the musculoskeletal system in man.** *Circulation Res.*, 1955, **3,** 483–489. [Radioisotope Unit, Veterans Admin. Hosp., Seattle, Wash.]

LEEVY, C. M. and DONOVAN, F. J. **Estimation of total circulating sodium.** *J. Amer. Med. Assoc.*, 1955, **159,** 771–773. [Dept. Med., Jersey City Med. Centre, N.J.]

Total circulating Na estimated by measuring the concentration in serum and the plasma volume was on the average 6·0 m. equiv. per kg. bodyweight in 13 normal subjects. Values ranged from 3·0 to 12·4 in 92 patients with abnormalities of body Na. Specific diseases had no characteristic pattern. Low blood Na due principally to either salt depletion or to primary water retention can be distinguished by the estimation of total circulating Na. This estimation also makes it easier to recognise a deficit in plasma Na with a normal serum concentration.—A. Hepburn.

1492

WOLF, F., KINZLMEIER, H. and KIENAST, W. Die photoelektrische Bestimmung der mineralischen Alkalireserven des Serums. **[Photoelectric estimation of the mineral alkali reserve in the serum.]** *Münch. med. Wochenschr.*, 1955, **97,** 1722–1724. [Med. Klin., Univ. Erlangen.]

A satisfactory photo-electric estimation of serum alkali reserve, suitable for clinical use, was obtained after precipitation of protein with methanol. The results agreed well with those obtained by the Van Slyke gas analysis method in healthy subjects and in patients with lipaemia,

ketosis and alkalosis. In 111 normal subjects the alkali reserve ranged from 46·59 to 55·55 vol. per cent. CO_2.—A. M. Copping.

1493

GRÄSBECK, R. **Fractionation of human gastric juice and saliva employing starch electrophoresis.** *Gastroenterologia*, 1955, **84,** 99–102. [Dept. Biochem., Sch. Hyg. Pub. Health, Johns Hopkins Univ., Baltimore, Md.] German and French summaries.

After removal of mucus by centrifuging, the juice was dialysed and lyophilised. The solid obtained was dissolved in a small volume of buffer, *p*H 4·5 to 6·1, and subjected to electrophoresis in a vertical starch block. This was then cut into 35 pieces and each was tested for protein, glucosamine, hexuronic acid and vitamin-B_{12}-binding power. Peptic activity was shown to accompany the major protein peak.—H. G. Bray.

1499

GARN, S. M. and CLARK, L. C. (Jr.) **Creatinine-weight coefficient as a measurement of obesity.** *J. Appl. Physiol.*, 1955, **8,** 135–138. [Fels Res. Inst., Antioch Coll., Yellow Springs, Ohio.]

The subjects were 76 men aged from 20 to 59 years and weighing from 51·8 to 139·6 kg. Creatinine excretion per 24 hr. was measured and estimates of thickness of subcutaneous trochanteric fat and of percentage of total body fat were made by the authors' methods (see Absts. 1982 and 5132, Vol. 24). Correlations between the creatinine-weight coefficient and trochanteric and percentage fat were moderate, $r = -0{\cdot}43$ and $-0{\cdot}40$, respectively. Further examination of the data revealed that the coefficient failed to identify all obese subjects because some men excrete relatively small amounts of creatinine. The ratio was more effective as a measure of leanness than of obesity.—D. Harvey.

NICHOLS, P. J. R. and BAILEY, N. T. J. **The accuracy of measuring leg-length differences. An "observer error" experiment.** *Brit. Med. J.*, 1955, ii, 1247–1248.

An experiment was made to examine the accuracy of the standard technique for measuring differences in leg lengths. A group of 50 subjects was selected at random from patients at the Royal Air Force Medical Rehabilitation Unit, and included a number where differences in the lengths of the legs might be expected. The difference for each subject was measured independently by each of 4 doctors, being recorded to the nearest quarter-inch. Analysis of variance of the results showed that there were statistically significant differences between the results obtained by the 4 doctors, but the corresponding estimated component of variance was only 0·006, which is small compared with the residual experimental error of variance of 0·0155. Thus in practice there is scarcely any more variability between measurements by different observers than between repeat measurements by a

single observer. The experimental error is such that differences of ½ in. or more may be taken as diagnostically significant, but smaller differences are not conclusive unless based on a number of measurements.—I. McDonald.

1502

HARPER, R. **Fundamental problems in the subjective appraisal of foodstuffs.** *Appl. Statistics*, 1955, **4**, 145–161. [Dept. Psychol., Univ. Leeds.]

This paper surveys the whole question of the subjective appraisal of foodstuffs, from its techniques to its epistemology. After listing the types of information which may be required, it comments on the main methods of obtaining them: from laboratory panels, from commercial graders or from consumer research. Many trade practices have been established as a result of long experience, but they are usually disturbed by the very process of investigation and it is difficult to estimate their efficiency. It is easier to assess the effect of special training, and a number of investigations have shown that it may greatly increase the sensitivity of some persons. Investigation has also revealed a number of extraneous conditions which may bias the judgement of a single sample. These include the memory of samples tested just before, and even the marking labels used to identify the sample. In the past, subjective judgements have been underrated, owing partly to lack of understanding that because of their complex nature they are seldom highly correlated with any single physical or chemical measurement. It is now recognised that they are extremely useful for some purposes, and can be quite satisfactory when made by a suitably standardised technique. There is finally a philosophic discussion of the problem of drawing conclusions about reality from observations, and it is questioned whether the statistical models in present use are adequate to deal with the complex situations arising when foodstuffs are studied in this way.—I. McDonald.

KOLARI, O. E., RUTLEDGE, E. A. and HANSON, L. E. **New equipment for baby pig metabolism studies.** *J. Animal Sci.*, 1955, **14,** 636–641. [Univ. Minnesota.]

An adjustable harness made of elastic, with a collection bag for faeces, suitable for use with pigs too young for confinement in metabolism crates, and also an apparatus for collection of urine from male piglets which allows freedom of movement, are described, with diagrams and photographs.

T. D. Bell.

1513

RAYMOND, W. F. and MINSON, D. J. **The use of chromic oxide for estimating the faecal production of grazing animals.** *J. Brit. Grassland Soc.*, 1955, **10,** 282–296. [Grassland Res. Inst., Hurley, Berks.]

Conditions affecting the accuracy of methods of estimating faecal output on pasture by means of chromic oxide are discussed, and the method of analysis used in the experiments reported is described.

It was shown first that chromic oxide did not impede the digestion of herbage by sheep. Giving the marker in gelatine capsules or as a drench did not alter the diurnal pattern of its concentration in the faeces. This pattern was shown not to be constant, varying with the digestibility of the herbage and the level of intake. From this it was concluded that grab sampling was not suitable. A more satisfactory method, called "ring sampling", is described, in which the faeces dropped within certain marked areas are collected periodically and analysed. When total faecal production was established by this method the results agreed well with those obtained by total collection. The effects of time and method of dosing, and rate of passage of feed through the intestine, on the daily pattern of chromic oxide concentration in the faeces are discussed.—T. D. Bell.

1514

SCHNEIDER, W. Beitrag zur Durchführung von Verdauungsversuchen bei Schweinen mit Hilfe der Indikatormethode. 1. [**Technique of digestion experiments with pigs by the indicator method. 1.**] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10,** 269–274. [Inst. Tierernährungslehre, Landw. Hochsch. Stuttgart-Hohenheim.] English summary.

Digestion experiments were made with 2 pigs, castrated males of the Swabian-Halle breed weighing about 120 kg., to compare the chromic oxide indicator method with the conventional. Cr was estimated by the method of Schürch *et al.* (Abst. 3204, Vol. 20) with precautions to diminish loss of Cr during mixing of faeces.

In the first experiment, the daily ration was ground barley 2000, protein concentrate 500 and chromic oxide 10 g., given as a thick slop in 2 feeds, for a pre-period of 10 days and an experimental period of 10 days. Daily analyses of faeces showed that their amount was much more variable than their composition. The digestion coefficients found by the indicator method were slightly lower than by the conventional method, probably owing to loss of Cr during preparation of faeces for analysis, but the discrepancy was considered unimportant for most purposes. From combinations of the results in different ways it was concluded that in most experiments collection of faeces over 3 days would suffice.

In the second experiment, lasting 8 days, with the same pigs and a daily ration of tapioca meal 1000, maize 1000, ground extracted soya 500, fishmeal 100 and chromic oxide 10 g., the faeces were sampled at random instead of being collected quantitatively. This proved unsatisfactory; the results agreed neither among themselves nor with those of the conventional method. Further studies are planned.—W. M. Deans.

1515

DEIJS, W. B. and BOSMAN, M. S. M. **Plant pigments in digestion trial studies.** *Rec. Trav. chim. Pays-Bas*, 1955, **74,** 1207–1216. [Central Inst. Agric. Res., Wageningen.]

In digestibility studies with cattle, plant pigments used as markers were extracted from grass and faeces with 85 per cent. aqueous acetone containing oxalic acid, 0·03 *M*. The pigments in the

extract were separated chromatographically on alumina into carotene, xanthophyll, phaeophytin and porphyrin fractions. The porphyrins constituted from 2 to 7 and from 30 to 50 per cent. of total pigments extracted from fresh grass and faeces, respectively. Phylloerythrin was separated from the other porphyrins and identified spectrophotometrically.

Acid acetone extraction, resulting in alteration of chlorophylls to the more stable phaeophytins, was preferred to extraction with aqueous acetone alone, the method of Reid *et al.* (Abst. 1460, Vol. 20). Digestibility coefficients of crude protein by the acid extraction marker method were in good agreement with those calculated by Dijkstra's method (*Landbouw*, 1951, **13,** 23).

Since analyses of base, middle and upper parts of tall grass separately revealed a positive correlation between the content of chromogen and that of crude protein, it was concluded that the error due to the grass sample differing from that eaten by the animals was not important.—J. Davidson.

COOKING, STERILISATION AND PRESERVATION OF FOOD

1517

TOLLENAAR, F. D. and DEN HARTOG, C. Chemicaliën in voedingsmiddelen, een brandend probleem. Indrukken naar aanleiding van een in Wenen gehouden symposium. [**Chemicals in foods, a burning problem. Impressions from a symposium in Wenen.**] *Voeding*, 1955, **16,** 923–932. [Centraal Inst. Voedingsonderzoek T.N.O., Utrecht.]

The symposium was organised by the *Commission Internationale des Industries Agricoles* (C.I.I.A.) and the *Bureau International Permanent de Chimie Analytique*, which deals with foods and feedingstuffs, as the first of a series of four to deal with the addition of chemicals to food. The meeting, 6 to 11 July, discussed chiefly colouring matter with special reference to carcinogens. A "working paper" prepared for discussion at the next meeting proposed: (1) that foreign substances should not be permitted unless their probable harmlessness had been demonstrated; the addition was defensible on economic and technical grounds; only minimum quantities were used, and the addition should not deceive the buyer about the quality of the food: (2) additions to staple foods should not be allowed, *i.e.*, to milk and milk products, flour and bread, meat and meat products, lard, fresh vegetables and fruit; (3) international agreement is urgently required on a list of permissible additions; (4) addition should be declared on the package; (5) it is desirable that all foods marketed with permitted additions should be procurable also without them.—I. Leitch.

SOUCI, S. W. Zur Färbung und Konservierung der Lebensmittel. [**Colouring and preservation of foods.**] *Deutsch. med. Wochenschr.*, 1955, **80,** 1761–1765. [Deutsch. Forschungsanst. Lebensmittelchem., Munich.]

This report of a lecture to the Consumers' Council of the Ministry of Nutrition, Agriculture and Forestry on colours, preservatives and other extraneous substances added to foods includes some of the findings of 3 Commissions set up in Germany in recent years with a view to new and stricter food laws, and of the international conference held at Bad Godesburg in May 1954, with lists of substances considered permissible. The use of β-carotene to colour butter is commended, and riboflavin is also suggested as a colouring matter.—W. M. Deans.

SAGER, C. A. Untersuchungen über Struktur und Haltbarkeit der gefriergetrockneten Frauenmilch. [**Structure and keeping quality of freeze-dried human milk.**] *Monatsschr. Kinderheilk.*, 1955, **103,** 469–471. [Kinderklin., Univ. Kiel.]

The milk was frozen at — 20° C. in feeding bottles, and dried by high-vacuum pump at — 60° C. In the process it lost 89·3 per cent. by weight. The milk powder was stored in the dark at room temperature. After 3 months' storage the lipase, phosphatase and amylase activities were unimpaired, and the power of the milk to inhibit the growth of micro-organisms was at least partly retained. Electrophoresis on paper showed that there was no denaturation of the protein such as occurs in heated milk. The haemagglutination test was still positive. The fat retained its properties well but did not re-emulsify with water very readily; it required slow treatment with water at 30° C. Lactose and Ca were unchanged.

KRUISHEER, C. I. and KROL, B. M. **The effect of the copper content on the development of flavour defects in cold-stored butter.** *Nederlands Melk Zuiveltijdschr.*, 1955, **9,** 173–181. [Govt. Dairy Stat., Leyden.] Dutch summary.

Studies of flavour defects in representative monthly samples of cold-stored unsalted butter made from ripened cream showed that contamination with copper is even more important than was previously supposed (Abst. 3149, Vol. 19). In summer butter the correlation between Cu content and off-flavour score was $r = + 0{\cdot}67 \pm 0{\cdot}07$. Cu was estimated by the method of den Herder and Krol (Abst. 3138, Vol. 20). Off-flavours began to appear with 50 μg. Cu per kg., which is about the amount naturally occurring in summer butter, and fatty, fishy or fish-oil flavours were present in all but one of the samples with 70 μg. Cu per kg. These findings are similar to those of Piraux *et al.* in Belgium (*Bull. Inst. agronom. Gembloux*, 1954, **22,** 76). In winter butter, which generally contains more Cu, the association with off-flavours was much less clear.

The tocopherol, carotene and vitamin A contents are stated to have no detectable effect on keeping quality (Kruisheer, *Nederlands Melk Zuiveltijdschr.*, 1955, **9,** 275.)—W. M. Deans.

POL, E. Zhirnyi syr i tvorog bez molochnogo zhira. [**Fat cheese and curds made without milk fat.**] *Mol. Prom.*, 1955, **16,** No. 6, 42–43. [Cheese Factory, Schmiedeberg, East Germany.]

Vegetable oil replaced milk fat in the making of cheese and curds. The vegetable oil was emulsified either by making a mayonnaise-like emulsion with egg yolks, 2 yolks to 1 kg. vegetable oil, which was then diluted in the defatted milk, or by the use of a separator or homogeniser. The amount of vegetable oil needed was calculated by taking 1 kg. vegetable oil to equal 970 g. pure milk fat. Groundnut, sunflower and cotton oils were found to be the most suitable; they were deodorised and refined before use. Only soft cheese could be produced by this method. There was a slight after-taste when the cheese had been swallowed. The relation of this cheese to ordinary cheese is said to be the same as that of good margarine to butter. Vegetable oil being cheaper than milk fat, the resulting cheese costs less. Its final value and that of the curds made with vegetable oil lies in its readily absorbed Ca compounds and protein.

LÜCK, H. and JOUBERT, F. J. Der Einfluss verdünnter H_2O_2-Lösungen auf Molkenproteine. [**Effect of dilute hydrogen peroxide solutions on whey proteins.**] *Biochem. Ztschr.*, 1955, **327,** 221–230. [Dairy Indust. Control Board, Windhoek, South Africa.]

Previous work by the same authors (*Milchwissenschaft*, 1955, **10,** 160 and in the press) on the

preservation of milk with dilute hydrogen peroxide showed that casein dissociated. The present paper deals with crystallised β-lactoglobulin and β-lactoglobulin in freeze-dried whey prepared by methods described from centrifuged milk to which 0·25 or 1 per cent. of 40 per cent. H_2O_2 was added.

Examination by the Tiselius apparatus for electrophoresis and the ultracentrifuge showed slight changes in crystalline β-lactoglobulin stored for 7 days at 4° C. with 1 per cent. of H_2O_2. Serum albumin used for comparison was unaffected. On electrophoresis of whey, however, the mobility of β-lactoglobulin was reduced and its peak was broadened by treatment for 6 days with 0·25 per cent. of H_2O_2 and split into 2 by treatment with 1 per cent. of H_2O_2; and ultracentrifuged whey gave a sedimentation diagram indicating dissociation of the β-lactoglobulin. The immune globulins seemed to be unaffected. Why β-lactoglobulin in whey should be so much more sensitive than the pure substance is not clear. Fresh casein-free whey with 1 per cent. of H_2O_2, when examined by Beckman spectrophotometer, showed a flattening of absorption curves in the regions corresponding to tyrosine and tryptophan, more marked in light than in darkness.—W. M. Deans.

1529

RAUCH, W. Qualitätsprüfungen von geölten und ungeölten Hühnereiern. [**Tests of the quality of oiled and unoiled hen eggs.**] *Arch. Geflügelk.*, 1955, **19,** 453–463. [Bundesforschungsanst. Kleintierzucht, Celle.] English summary.

Eggs from the institute were dipped for 3 sec. in oil (Osagit, from Shell A.G., Hamburg) at 30° C. on the day after laying and were stored in a cellar at 17° C. and 74 per cent. relative humidity along with unoiled controls. Another experiment with cold storage at 2° to 3° C. is not yet complete. The results of studies of weight loss, height of air space, yolk height, yolk index, freezing-point of white and refractive index of white and yolk at intervals up to about 80 days are shown graphically. All these, except refractive index of yolk, which was little affected by oiling, as well as organoleptic tests, confirmed the finding of others that stored oiled eggs keep better than unoiled.

PARTMANN, W. Zur Frage der künstlichen Fleischreifung mit papainhaltigen Präparaten. [**Artificial ripening of meat with preparations containing papain.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **102,** 321–329. [Bundesforschungsanst. Lebensmittelfrischhaltung, Karlsruhe.]

In continuation of previous work (Partmann, *Naturwissenschaften*, 1955, **42,** 161) studies were made by phase contrast microscopy of homogenates of beef gastrocnemius muscle and of connective tissue which had been ripened by a papain preparation for from 15 min. to 24 hr. at 21° to 22° C. Changes in fine structure of muscle and contraction of fibrils on treatment with adenosine triphosphate are described. Although contractability was not immediately lost, appearance and consistency of the muscle homogenate changed soon after the ripening agent was added. Since the same was true of the connective tissue homogenate, and the percentage of free amino-acids, estimated by the method of Pope and Stevens (Abst. 2631, Vol. 9), rose in both homogenates at about the same rate, it was concluded that papain attacks the proteins of connective tissue as well as those of muscle fibres. The changes in natural ripening of meat may not be the same, and work on this is proposed.

SRIBNEY, M., LEWIS, U. J. and SCHWEIGERT, B. S. **Effect of irradiation on meat fats.** *J. Agric. Food Chem.*, 1955, **3,** 958–960. [Div. Biochem. Nutrit., Amer. Meat Inst. Found., Chicago, Ill.]

Rendered and non-rendered beef and pork fats, packed in casings permeable or non-permeable to oxygen or in cans with air space, were sterilised by γ-rays and stored at 5° C. (casings) or 24° C. (cans) for 4 weeks along with untreated control samples.

Peroxide values were increased by γ-ray treatment as well as by subsequent storage, especially in samples in casings permeable to oxygen. Fat in cans had lower peroxide values and higher free fatty acid values when the radiation dose was increased, which suggests that some cleavage of fatty acid peroxides occurs. No off-odour was noticed, so that it seems that fat is not responsible for the off-odours and off-flavours found when meat is sterilised in this way.—W. M. Deans.

CARACCIOLO, S. Ulteriori ricerche sulla resa in carne commestibile (cruda e cotta) di alcune specie di animali acquatici marini. [**Further researches on the amount of edible flesh (raw and cooked) of some species of marine and aquatic animals.**] *Zootec. Vet.*, 1955, **10,** 284–290. [Catt. Approvvig., Univ. Perugia.] French, English and German summaries.

The percentage loss of weight after successive stages of preparation, and the percentage edible flesh after cooking, of some species of fish, cephalopod and lamellibranch molluscs and crustaceans were estimated. The results are presented in tables. It was shown that, contrary to popular belief, the percentage of edible flesh was not inferior to that of domestic animals in most cases, although a wide variation was found between species. Cooking losses varied with the method.

PARIHAR, D. B. **Changes in the saccharides of wheat-flour and rice on their processing into some common Indian foods.** *Naturwissenschaften*, 1955, **42,** 514. [Defence Sci. Lab., Hill Side Rd., New Delhi.]

The saccharides in chapatis, bread, fried flour, rabri (a slurry product made by boiling flour with excess water), puffed rice and cooked rice were examined by circular paper chromatography. During cooking glucose and its polymers were attacked first; carbohydrates containing some other sugars were comparatively resistant. Bread contained glucose, fructose, sucrose, maltose, *iso*maltose, glucofructosan, raffinose, and maltotriose, -tetrose, -pentaose and -hexaose, and fried flour only sucrose, raffinose and glucofructosan. On boiling, rice lost maltose, maltotriose and maltotetraose and glucose decreased. After 22 min. only sucrose and raffinose remained. Puffed rice contained only these 2 and maltose.

BOTHMA, F. De verwerking van retourbrood. [**The processing of unsold bread.**] *Het Bakkersvakblad*, 1955, No. 28, pp. 3. [Centraal Inst. Voedingsonderzoek T.N.O., Wageningen.]

In the United States the proportion of baker's bread unsold is estimated at 5 per cent. and in the Netherlands it is probably similar. In country districts the old bread probably goes to feed pigs and poultry, in the towns it is left in the bakers' hands. Processes in which such old bread is mixed into fresh dough are described. Up to 10 per cent. may be used, but colour and volume are inferior and keeping quality may be less good.

I. Leitch.

1538

BOTHMA, F. Gekookte aardappel in brood. [**Boiled potato in bread.**] *Het Bakkersvakblad*, 1955, **14,** No. 29, pp. 3. [Centraal Inst. Voedingsonderzoek T.N.O., Wageningen.]

A report in *Brot und Gebäk*, 1955, **9,** No. 4, p. 61 stated that the addition of boiled potato to dough improved the keeping quality of bread. To test this, bread was baked with 5, 10 or 15 per cent. potato. Staling was more, not less, rapid with potato than without. Loaf volume and quality were also less.—I. Leitch.

1540

KIERMEIER, F. and RICKERL, E. Über die Ursachen der Verfärbung gedämpfter Kartoffeln. 2. Der Einfluss des Eisens. [**Causes of discolouration of steamed potatoes. 2. Effect of iron.**] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **102,** 330–337. [Deutsch. Forschungsanstalt. Lebensmittelchem., Munich.]

The dull green colour produced when bivalent iron, from 0·1 to 10 mg. per 100 g. potato, was added to potato meal or dough increased with the amount and was more marked in the dough, showing that moisture also plays a part. Oxygen is already known to do so, and this probably explains why tervalent Fe was found to have less effect than bivalent. At *p*H values above 5·5 the colour was more intense. Addition of Cu or Mn did not blacken potato products.

Possible ways in which Fe may interact with chlorogenic and caffeic acids (see part 1, Abst. 188, Vol. 26) are discussed.—W. M. Deans.

NORDFELDT, S. (with KRUUS, K., HELLBERG, A., HANSSON, L., CAGELL, W. and RUUDVERE, A.) Ensileringsförsök. Prövning av kolhydratrika tillsatsmedel jämte salter av olika slag och AIV-vätska. [**Experiments in making silage. Tests with carbohydrate-rich additions, salts of different kinds and A.I.V. fluid.**] *Kgl. Lantbrukshögsk. Statens Husdjursförsök Medd.* No. 58, 1955, pp. 95. English summary.

The silos used, the laying down of the silage, and the several methods of recording temperatures, sampling for analysis, collection of drainage, analysis, and computation of losses and of the effect of the preservatives added are described. The first series of experiments was with small cylindrical silos, 40 cm. diameter × 80 cm. height and 100 litres capacity. The additions, all per 100 kg. crop, were: A.I.V. fluid 8 kg., molasses 3 kg., Ensilan 250 g., Kofa (see Abst. 4691, Vol. 25) 230 g., Siloferm (said to contain a culture of lactic acid bacteria) 15 g. with 3 kg. barley meal. There were 5 replicates of each and 5 controls without addition. The analyses include dry matter, organic matter, crude protein, ether extract, N-free extract, fibre, ash, Ca, P, sugar and carotene; organic acids and ammonia, *p*H, CO_2. In all, 550 lots of silage were laid down in these and bigger containers and in silos of capacity 8 to 10 tons. The crops, which were sometimes wilted, were from clover and grass pasture usually cut at budding or flowering, or, as typical of material difficult to deal with, alfalfa and clover before budding; the additions, as well as those shown above, were oatmeal, dried beet pulp, and Reymersholm silage phosphate (see Abst. 1168, Vol. 26). The results and computations are set out in detail.

The conclusions are: 5 or 6 per cent. dried beet pulp with molasses gives good quality silage with little loss, as do also cereal meals. Molasses should not be used unless with a wilted crop. Wilted grass gives better results than fresh. Of the chemical preservatives, A.I.V. fluid and Reymersholm phosphate give the best results with small silos. With the big silos, wilted crops and chopped material, the salts gave no improvement over ensiling without addition. The experiments continue.—I. Leitch.

1544

ALLRED, K. R., KENNEDY, W. K., WITTWER, L. S., TRIMBERGER, G. W., REID, J. T. and LOOSLI, J. K. **Effects of preservatives upon red clover and grass forage ensiled without wilting. 1. Storage losses.**

WITTWER, L. S., TRIMBERGER, G. W., KENNEDY, W. K., ALLRED, K. R., REID, J. T., LOOSLI, J. K. and TURK, K. L. **2. Feeding value.** *Cornell Univ. Agric. Exp. Stat. Bull.* No. 912, May 1955, pp. 35; *Bull.* No. 913, July 1955, pp. 30.

1. The use of 70 lb. molasses, 100 lb. brewer's grains or 9 lb. Na metabisulphite per ton forage did not reduce storage losses in clover-grass silage made in towers compared with those in silage made without preservatives sufficiently to warrant their use. Molasses and brewer's grains increased feeding value for cattle a little, but not as much as they would have done if given as fresh supplements to the cattle.

2. Silages similar to those just described were used in trials with 32 dairy cattle. There was no significant difference between the silages in amount consumed, production of 4 per cent. fat-corrected milk or digestibility of dry matter.

Molasses improved palatability, and the unattractive smell could be avoided with Na metabisulphite, but these were the only advantages, and no economic benefit resulted.—T. D. Bell.

BARNETT, A. J. G. **The effects of the addition of a poly-halogenated acetate of ethyl glycol on the fermentation of minced grass and water mixtures.** *J. Sci. Food Agric.*, 1955, **6,** 716–721. [Div. Agric. Biochem., Dept. Biol. Chem., Univ. Aberdeen.]

The glycol compound, widely used in France, is neutral and bacteriostatic. It was added to slurries of minced grass and water in aspirator jars at levels of 0·006, 0·09 and 0·18 per cent. (w/v). At the lowest level changes in *p*H and production of lactic acid, volatile fatty acids and bases were similar to those of the control (no additive). At the 2 higher levels lactic acid production was partly inhibited and *p*H remained higher than control. Volatile fatty acids and bases were formed in smaller amounts. At all levels the extent of amino-acid breakdown was reduced.—J. L. Corbett.

1547

ZUBKOVA, R. D. Rol' drozhzhei v silosovanii kormov. [**Role of yeasts in the ensilage of fodders.**] *Mikrobiologiya,* 1955, **24,** 353–358.

See also Absts. 1396, 1556, 1559, 1560, 1616, 1663–65, 1698, 1789, 1816–18, 2245.

CULTURE OF MICRO-ORGANISMS FOR FOOD

MORRIS, E. O. **Seaweed as a source of yeast food. 1. 2.** *J. Sci. Food Agric.*, 1955, **6**, 611–618; 618–621. [Brewing Indust. Res. Found., Nutfield, Redhill, Surrey.]

1. A detailed account is given of tests of seaweeds (*Laminaria cloustoni* frond and stipe, *Ascophyllum nodosum*, *Gigartina stellata*, *Polysiphonia fastigiata* and *Rhodymenia palmata*) and seaweed constituents (laminarin, fucoidin, D-mannitol, sodium alginate, and D-fucose), in the form of aqueous extracts without or with ammonium and magnesium sulphate and potassium dihydrogen phosphate, as media for the growth of 46 yeasts, of which 5 grew well enough to merit further investigation. A strain of *Oospora lactis* on the whole gave the best yields and extracts of *L. cloustoni* frond were the best media. Aeration of cultures slightly improved growth; temperature and method of sterilising extracts were without effect. Treatment of seaweed with 0·1 *N* or *N* HCl did not give better results, and chromatography confirmed that hydrolysis of the polysaccharides of the seaweeds had not taken place; it is concluded that other means of hydrolysis must be found before seaweed can be profitably used as a substrate for yeast.

2. Several enzymes were tested on pure laminarin and seaweed extracts; extract of malt and a filtrate of the cellulose-decomposing fungus *Myrothecium verrucaria* were found to hydrolyse up to 56 per cent. of the laminarin or the complex polysaccharides of seaweed. The treated seaweed gave excellent growth and fermentation of yeast, but high concentrations of the enzymes are required.

1549

INSTITUTO NACIONAL DE LA NUTRICION, QUITO. Tabla de composicion de alimentos ecuatorianos. **[Tables of composition of equatorial foods.]** *Bol. Informaciones Cient. Nac.*, 1955, No. 68, pp. 10.

Tables are presented of the composition of 272 foods, some prepared, in daily use in South America. Data on moisture, energy, protein, ether extract, total carbohydrates and fibre, ash, carotene, ascorbic acid and some of the B vitamins are included.—T. D. Bell.

1550

EDWARDS, C. H., CARTER, L. P. and OUTLAND, C. E. **Cystine, tyrosine, and essential amino acid contents of selected foods.** *J. Agric. Food Chem.*, 1955, **3**, 952–957. [Carver Found., Tuskegee Inst., Ala.]

Twelve amino-acids were estimated microbiologically in 25 foods commonly used in southeastern United States. The types of food were cereals 3, nuts 2, pork muscle and offals 9, egg and chicken offals 4, vegetables 7. The amounts of essential amino-acids in 2 typical southern dinners were calculated and compared with Rose's estimates of minimum daily requirements (Abst. 3891, Vol. 19).—D. Harvey.

1551

REITH, J. F. **Toxic trace elements in food; desirability and possibility of statutory regulations in this field.** *Voeding*, 1955, **16**, 832–838; 867–879; 932–943. [Dept. Food Chem. Toxicol., Univ. Utrecht.]

A review dealing with arsenic, barium, copper, fluorine, mercury, lead, selenium, tin and zinc occurring naturally or as contaminants in foods, with references, details of existing laws in several countries and principles on which further legislation should be based. Provisional limits are suggested for As, Fl, Hg, Se, Pb, Sn and Zn; Ba is considered unlikely to give trouble at present; Cu is kept low in some foods owing to its bad effect on quality, but may require control in vegetables and fruits because of its use in sprays. Up-to-date information on trace elements in Dutch foods is badly needed, but should await the establishment of reliable analytical methods, meanwhile the subject of consultation by the Trace Elements Commission of the International Union of Pure and Applied Chemistry.—W. M. Deans.

MACY, I. G., KELLY, H. J. and SLOAN, R. E. **The composition of milks. A compilation of**

the comparative composition and properties of human, cow, and goat milk, colostrum, and transitional milk. *Bull. Nat. Res. Counc., Washington*, No. 254, revised 1953, pp. iv + 70.

In this revision of Bulletin 119 of the National Research Council (see Title 183, Vol. 21), data from 268 papers have been assembled in tabular form to give the mean, minimum and maximum recorded values for 10 physical properties, 10 fat characteristics, and 258 chemical components of human, cow and goat milk.—F. E. Hytten.

1553

STRANSKY, E., DAUIS-LAWAS, D. T. and LAWAS, I. L. **On the protein level of milk in Filipino nursing women.** *J. Philippine Med. Assoc.*, 1954, **30,** 647–650. [Dept. Paediat., Coll. Med., Univ. Philippines.]

Protein was estimated in random samples of milk of 127 Filipino nursing mothers in different stages of lactation.

Six women with failing lactation had values of over 3 per cent., but apart from them the average value was 1·34 per cent. More than half had values between 1·0 and 1·5. The percentage with lower values was 18·1 and with higher values 27·5. The values are considered to compare well with those recorded in America and Europe, but babies fed exclusively on breast milk after the age of 6 months do not receive enough protein. The weight curve of Filipino babies tends to flatten at 6 months. No influence on the protein value of age or parity of the mother or of duration of lactation was apparent.—E. M. Hume.

PARADISO, M. and LA CAUZA, C. La gonadotropina corionica quale nuovo mezzo terapeutico per il trattamento dell'eccesso di grasso nel latte umano. [**Chorionic gonadotropin as a new means for treating excess of fat in human milk.**] *Lattante*, 1954, **25,** 687–689. *Proc.* [Clin. Pediat., Florence.]

See Abst. 4697, Vol. 25.

1555

DE LUCA, R. and CUTRONEO, A. Indagini elettroforetiche sulle proteine del latte di donna. [**Electrophoretic investigation of the proteins of human milk.**] Comportamento elettroforetico delle proteine del colostro di donna. [**Electrophoretic behaviour of the proteins of human colostrum.**] *Bol. Soc. ital. Biol. sper.*, 1955, **31,** 203–205; 206–208. [Ist. Clin. Pediat., Univ. Messina.]

Milk was collected 3 hr. after the last feed from 21 women in different stages of lactation. It was centrifuged and the serum, after filtration, treatment with animal charcoal, and dialysis, was subjected to electrophoresis. Three fractions were then distinguished; the proportion of them remained almost unchanged for 10 months, but between the 10th and 12th months there was considerable increase of fraction 3 at the expense of fractions 1 and 2.

Colostrum taken from 5 women 24 hr. after parturition and on the 4 ensuing days was investigated in the same way. The proportions of fractions 1 and 2 were greater, and of fraction 3 less, in colostrum than in milk, but by the 5th day they had progressively adjusted themselves to the values found in milk.—E. M. Hume.

1556

DAVIDOV, P. B. and ANISIMOVA, V. K. Soderzhanie ioda v moloke. [**The iodine content of milk.**] *Izv. Timiryaz Sel'skokhoz. Akad.*, 1954, No. 2, 47–54. [Timiryazev Agric. Acad.]

A study of the variation of iodine content throughout lactation. Tests were made on milk from the academy farm, both on mixed daily samples and on samples from individual cows. Further samples were taken at the Moscow Gor'ki milk combine on arrival of the milk at the combine and from milk sent out to consumers after treatment. The cows on the academy farm were pure-bred Kholmogors, average milk yield 5000 to 5500 kg. milk per cow. During the experiment the average annual amount of fodder per cow was 9 tons green fodder, 5 tons succulents and 2 tons coarse fodder and concentrates. Mineral supplements were provided in the form of salt, bone- and fishmeal and chalk. The lactation was arbitrarily divided into 3 periods: colostrum, 10 days, normal lactation, 290 to 320 days, and the period before drying-off, 5 days.

Colostrum had the highest iodine content; the lowest was before drying-off. If the average iodine content in the colostrum was taken as 100, then during the period of normal lactation the iodine content was only 42 and before drying-off 21 per cent. Although all the animals received the same rations and calved almost simultaneously (January and February) there was considerable variation in the iodine content of the milk of the different cows, one cow having an average of 320 and another only 86 μg. per litre. The maximum amount of iodine in the colostrum occurred in the first 2 days after calving; on the ninth and tenth days there was only about one-third as much as on the second day. It is therefore considered important, in view of the value of iodine for newly born animals, for calves to be given their dam's colostrum. There is 1·5 times as much iodine in the milk when the cows are stall-fed as when they are on pasture. Technological treatment and pasteurisation in particular was found to reduce the amount of iodine in milk by 22 per cent. on the

average. Milk examined on entering the Gor'ki milk combine showed an iodine content of 62 μg. per kg. ; on leaving the combine for delivery to the consumer it was 49, 79 per cent. of the original value.—H. Scherbatoff.

1557

VAN KOETSVELD, E. E. Het anorganisch sulfaat in rundermelk, -biest en -bloed. [**The inorganic sulphate content of the milk, colostrum and blood of cows.**] *Nederlands Melk Zuiveltijdschr.*, 1955, **9**, 165–172. [Inst. Moderne Veevoeding "De Schothorst", Hoogland.] English summary.

The inorganic sulphate of milk has been little studied.

Milk was freed from protein with trichloroacetic acid. The inorganic sulphate was precipitated from the protein-free filtrate with benzidine ; the benzidine sulphate was dissolved and diazotised ; with thymol a red colour was obtained, which could be measured by spectrophotometer at 500 mμ.

Milk samples from 8 cows contained from 7·0 to 14·6 mg. inorganic sulphate per 100 ml., mean 10·9, and the highest yields of milk were associated with the lowest sulphate concentrations, though the daily output of inorganic sulphate varied directly with the milk yield. In 4 cows in full milk production, giving from 15·8 to 27·4 kg. daily with from 9·0 to 9·9 mg. sulphate per 100 ml., and in 4 at the end of lactation with yields of 3·9 to 9·1 kg. and sulphate contents from 11·1 to 17·4 mg. per 100 ml., the mean serum sulphate values were the same, 14·7 mg. per 100 ml. Colostrum of 3 cows was low in sulphate, one cow giving 0 and 3·5 mg. per cent. in the evening and morning milk, respectively, on each of the first 2 days after calving.

Four samples of human milk contained only from under 0·5 to 2·5 mg. inorganic sulphate per 100 ml.—D. Duncan.

1558

RAJ, H. and JOSHI, N. V. **Amino-acid composition of the milk of Indian buffaloes. 1. Essential amino-acid composition of total proteins and protein fractions. 2. α- and β-casein components.** *Indian J. Med. Res.*, 1955, **43**, 591–596 ; 597–602. [Nat. Chem. Lab., Poona.]

1. Two samples of mixed milk and 6 samples from buffaloes of each of the 2 breeds, Surti and Delhi, were collected. Total milk protein, whole casein and total whey protein were analysed by microbiological methods for 8 essential amino-acids and for cystine. The data are tabulated. Little difference from data published for cow's milk was found.

2. Fractionation was by the method of Warner (*J. Amer. Chem. Soc.*, 1944, **66**, 1725). Tryptophan, *iso*leucine and lysine were higher in α- than in β-casein ; leucine, methonine, threonine and valine were higher in β- than in α-casein. In comparison with the data of Gordon *et al.* (Abst. 4581, Vol. 19) these fractions of buffalo's milk differed little from those of cow's milk.

D. Harvey.

1559

BERGE, S. Fettprosenten i geitemjølk. [**Percentage fat in goat's milk.**] *Sau og Geit*, 1955, No. 4, 85–86.

The composition of goat's milk as sampled at the Tretten cheese factory in 1932–33 and as recorded for the whole country in 1949 is given as, per cent. : total solids 12·20, 11·82 ; fat 3·75, 3·48 ; protein 3·10, 3·17 ; lactose 4·01, 4·33 ; ash 0·81, 0·83. English milk has more protein (3·34) and more fat (4·5) than Norwegian milk as reported by M. D. Gordon (1950) for the British Goat Association [no reference]. Lactose (4·08) is about the same. There is a low inverse correlation between lactose and fat.

The special value of goat's milk for cheese-making resides in the taste, and it is not known what substances cause the taste, whether strength of taste is a heritable characteristic of the goat, or whether, as some think, milk from goats fed indoors in clean stalls and giving a high yield has less taste than ordinary milk. In some countries breeders select against taste : in Norway selection should be for taste with yield and for lactose, since goat's milk protein and fat have no special value and fat may be present in excess of what cheese-makers prefer. Also, goat's milk costs more to produce than cow's milk.—I. Leitch.

1560

LINDSET, J. Fettprosenten i geitmjølk. [**Percentage fat in goat's milk.**] *Sau og Geit*, 1955, No. 5, 95–96.

The manager of a dairy replies to Professor Berge (see preceding Abst.). Real goat cheese requires 3·2 per cent. fat in milk and neither the fat nor the protein can be replaced by cow's milk fat or protein. It is true that goat's milk costs more to produce ; it is still most profitable when both yield and fat percentage are high. In northern Norway the milk is often of poor quality, low in fat and total solids.

Taste is associated with both the fat and the sugar, not with the protein, but the characteristics of goat's milk protein are different from those of cow's milk protein and the cheese produced is much finer. It does not depend on type of housing but does, to some extent, depend on the feed ; individual differences are certain.

In a postscript Berge replies briefly, on the assumption that goat's milk cheese should have a fixed proportion of lactose, protein and fat. More information is needed.—I. Leitch.

1561

KASANEN, A., EKMAN, E. M. and PELTONEN, T. Über den Eisengehalt in der Milchnahrung der Säuglinge. [**Iron content of milk feeds for infants.**] *Ann. Paediat. Fenn.*, 1955, **1**, 277–282. [Kinderklin., Univ. Turku.]

The Fe content, as estimated by Wong's method, of the milk of 101 donors to milk banks in 4 towns of Finland ranged from 0·051 to 0·144 mg. per cent., mean 0·085. Other results are quoted from the literature. The mean value on the first day for 40 women delivered in the university hospital was only 0·053 mg. per cent. It rose rapidly in the next few days and then more slowly to a maximum in the 4th month, and after 6 months declined a little. Age of mother and delivery by caesarean section made no difference.

Although cow's milk naturally contains less Fe than this, in practice it takes up enough from containers to approach human milk ; milk on sale in Turku had a mean Fe content of 0·079 mg. per cent. Infant feeds used in the *Kinderklinik* had more : two-thirds milk, with 3 per cent. wheat flour, 0·097, half-milk, diluted with oatmeal gruel, 0·103 and full milk with egg, 0·104 mg. per cent.

1562

STADHOUDERS, J. and MULDER, H. **The composition of Dutch butter fat. 1. Seasonal variations in the unsaturated fatty acid composition of butter fat.** *Nederlands Melk Zuiveltijdschr.*, 1955, **9**, 182–193. [Lab. Dairying, Agric. Univ., Wageningen.] Dutch summary.

At fortnightly intervals during 1953–54, 27 butter samples were obtained from a co-operative dairy and the butterfat was examined for poly-unsaturated fatty acids, iodine value and refractive index ; residual unsaturation, after allowing for the contribution of the polyunsaturated fatty acids to the iodine value, was calculated as oleic acid.

The following ranges of values, expressed as weight per cent., were found : dienoic acids, conjugated, 0·58 to 2·81 ; dienoic acids, non-conjugated, 0·73 to 1·90 ; trienoic acids, conjugated, 0·015 to 0·026 ; trienoic acids, non-conjugated, 0·35 to 0·96 ; tetraenoic acids, conjugated, 0·0 to 0·008 ; tetraenoic acids, non-conjugated, 0·27 to 0·60 ; oleic acid, 28·1 to 40·1 ; iodine value, 32·1 to 46·6.

With the change-over from winter stall-feeding to pasture in May the content of oleic acid, conjugated dienoic acids and non-conjugated trienoic acids in butterfat rose appreciably ; that of non-conjugated dienoic acids fell. The content of oleic acid, the iodine value of the fat and its refractive index were closely correlated throughout the year.—G. A. Garton.

1563

MULDER, H. and SCHOUTEN, G. Het "Zoutgehalte" van enige soorten dieetkaas uit de handel. [**"Salt" content of some kinds of "dietetic" cheese on the market.**] *Voeding*, 1955, **16**, 976. [Lab. Zuivelbereiding, Landbouwhogesch., Wageningen.]

"Dietetic" cheese is designed for use in unsalted therapeutic diets. Data are given for the percentage of Na, K, Ca and Cl in 6 samples of cheese bought in the open market. Unsalted cheese had 0·03 per cent. Na, ordinary Edam cheese 0·78. Of "dietetic" cheeses one hard cheese had 0·06 and one cream cheese 0·05 per cent. Na. The other two, which had presumably been treated in the usual way with sodium citrate and sodium phosphate to soften them, had 0·67 and 0·66 per cent. Na.—I. Leitch.

Meat (All Kinds)

1564

WENIGER, J. H., FUNK, K. and KÖNIG, K. H. Untersuchungen über den Calcium-, Phosphor- und Nährstoffgehalt von Schafen und Ziegen. [**Calcium, phosphorus and organic nutrients in sheep and goats.**] *Arch. Tierernährung*, 1955, **5**, 216–224. [Inst. Tierzucht, Martin Luther Univ., Halle.]

The carcases analysed were those of 10 sheep, some of the Merino and some of the Karakul breed, ranging from newborn lambs to 10 years of age, and of 7 goats of the Improved White breed, ranging from newborn kids to 3 years of age. The carcases except those of newborn lambs and kids were subdivided into (1) blood and organs, (2) flesh and fat, (3) bones, (4) pelt. Dry matter, crude protein, crude fat, Ca and P were estimated as for pigs (Abst. 4272, Vol. 24). The results are given in tables in g. per kg. (liveweight less digestive tract contents) or as percentages ; some results by Lawes and Gilbert and by Jantzon (quoted from Radeff, *Arch. Tierernährung*, 1930, **3**, 639) for sheep are also reproduced.

Newborn lambs contained little fat, only about 1/6 of the protein content. The Ca : P ratio (mean of 4) was 1·75 : 1, close to the values for kids (1·78 : 1) and piglets (1·73 : 1). Animals of 9 months had much more fat but were similar in protein content and Ca : P ratio. At 21 months the Ca : P ratio was slightly greater. In all parts other than bones and pelt P was more abundant than Ca. The ash of the bones contained from 35·7 to 37·4 per cent. Ca and from 17·40 to 17·81 per cent. P. The ash content of the bones increased

with age. The results for kids and goats were similar to those for lambs and sheep.

W. M. Deans.

1565

MARSHALL, C. R. **The nitrogen content of lean pork.** *Analyst*, 1955, **80,** 776–778. [Excel Co., Ltd., Carpenters Rd., Stratford, London, E.15.]

From data which are tabulated for the composition of each of 5 cuts from 1 side of home-killed and 1 of Irish pork, N on a fat-free basis was calculated to be 3·39 and 3·43 g. per 100 g., respectively. For further analyses of only shoulders and loins from 5 sides the arithmetical means were 3·35 and 3·65 on the same basis. These are lower than the data reported by Jackson and Jones (*Analyst*, 1932, **57,** 562) on which are based the factors recommended by the Society of Public Analysts, Analytical Methods Committee (Abst. 1195, Vol. 23) for converting meat N into defatted meat. It is thought possible that either breed or changes in methods of feeding may have produced these differences between new and older values.

D. Harvey.

1566

TARANOVA, A. I., AL'BOVA, E. S. and GROMIKHINA, L. S. Soderzhanie arginina, gistidina, lizina, tirozina, triptofana i tzistina v belkakh razlichnykh vidov myasa i ryby. [**Arginine, histidine, lysine, tyrosine, tryptophan and cystine in the protein of different kinds of meat and fish.**] *Vop. Pitan.*, 1955, **14,** No. 5, 27–35. [Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

The composition in terms of 6 amino-acids is tabulated for 24 kinds of meat from domestic animals and birds or game, 20 kinds of fish and fish products and also dolphin, seal, lobster and crab.—D. Duncan.

1567

EASTOE, J. E. **The amino acid composition of mammalian collagen and gelatin. Notes on the determination of amino acids by ion-exchange chromatography.** *Biochem. J.*, 1955, **61,** 589–600; 601–602. [Brit. Gelatine Glue Res. Assoc., 2a Dalmeny Ave., London, N.7.]

The amino-acid composition of collagen or gelatine from man, ox, pig, whale and wallaby was estimated by a slightly modified form of the method of Moore and Stein (Abst. 4469, Vol. 21) which is described in the appendix (pp. 601–602).

The values for ox-hide gelatine agreed well with those previously published, except for alanine and serine. Two gelatines serially extracted from ox hide, which differed in rigidity properties but had the same molecular weight, were not significantly different in amino-acid composition. Gelatine had a composition similar to that of collagen. Collagens from man, ox and pig did not differ much, but collagen from wallaby contained slightly more serine and threonine, and these were present in greater amounts in whale gelatine. Gelatine contained less tyrosine than collagen precursors. Fractionation with ethanol further reduced the tyrosine content.—A. Hepburn.

1568

HANSEN, R. P., SHORLAND, F. B. and COOKE, N. J. **Occurrence of *n*-nonadecanoic acid in ox perinephric fat.** *Nature*, 1955, **176,** 882. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

An acid was isolated in trace amounts from hydrogenated ox perinephric fat which corresponded in its saponification equivalent, melting-point and X-ray long spacing to *n*-nonadecanoic acid.—G. A. Garton.

1569

SHORLAND, F. B. and JESSOP, A. S. **Isolation of Δ^9 heptadecenoic acid from lamb caul fat.** *Nature*, 1955, **176,** 737. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

By the use of methods which included low-temperature crystallisation, ester-fractionation and chromatography on silica gel, 1·846 g. C_{17} unsaturated fatty acid methyl esters, m.p. — 32° to — 30·5° C., was obtained from 2·5 kg. lamb caul fat. Hydrogenation of a portion of these esters, followed by saponification, yielded an acid, m.p. 59·5° to 60·5°, which gave mixed m.p. 60·0° to 60·6° on admixture with authentic margaric acid, m.p. 60·8° to 61·0° C. Oxidation of the unsaturated fatty acid with $KMnO_4$ yielded azelaic acid. It was therefore concluded that Δ^9-heptadecenoic acid was present in the lamb caul fat.—G. A. Garton.

1570

MERKER, P. C., EDWARDS, L. D., ANDREWS, F. N. and CHRISTIAN, J. E. **The estrogenic activity of residues obtained from chickens treated with pellets of diethylstilbestrol.** *Poultry Sci.*, 1955, **34,** 1118–1125. [Sch. Pharm., Purdue Univ., Lafayette, Ind.]

Fish

1571

LEE, C. F. **Composition of cooked fish dishes. Proximate analysis of dishes containing fish and shellfish.** *Fish and Wildlife Serv., U.S. Dept. Interior Circular* No. 29, pp. 31.

In this mimeographed circular proximate composition and energy value per 100 g. and per serving are tabulated for 161 cooked sea fish or shellfish dishes. The ingredients of composite dishes are given in household measures [but not the method of preparation].—W. M. Deans.

1572

GOROZHANKINA, L. A. Soderzhanie metionina v belkakh ryb i rybnykh produktov. [**Methionine content of protein of fish and fish products.**] *Vop. Pitan.*, 1955, **14,** No. 5, 35–37. [Inst. Pitan., Akad. Med. Nauk SSSR, Moscow.]

The methionine content of 21 kinds of fish and fish products was estimated. The percentage of total protein N provided by methionine ranged from 1·6 in sprats preserved in oil to 2·32 in pilchards. Other fish rich in methionine were sandre, cod, salmon, sturgeon and catfish.

D. Duncan.

1573

GUTTMANN, A. **Extracts and enzymic hydrolysates from fish liver and mammalian liver.** *J. Fish. Res. Board Canada*, 1955, **12,** 637–645. [Atlantic Fish. Exp. Stat., Halifax, N.S.]

Besides supplying other nutrients, beef liver was formerly a cheap source of good protein, but the price is steadily rising. Meanwhile large quantities of fish liver are discarded after the oil has been secured. Studies were accordingly made of extracts from fresh whole liver, liver residue after treatment of fresh minced liver with sodium bisulphite, autoclaving and centrifuging to remove the oil, or liver residue dried and defatted by extraction with 1 : 2-dichloroethane, and of enzymic hydrolysates produced from fresh minced liver by digestion with papain and removal of oil, or from dried defatted liver or liver residue by digestion first with papain and then with pancreatin. Details of the procedures are given. Ca, total and inorganic P, Cu, Fe, total N, amino-N, choline, vitamin B_1, riboflavin, folic acid, nicotinic acid, pantothenic acid and vitamin B_{12} contents of 7 extracts and 9 enzymic hydrolysates on a dry basis are tabulated; for most of the later Co and F contents are also given. The species represented were cod, salmon, haddock, whale and seal, with beef liver and pork liver for comparison.

The mineral, total N, amino-N, choline, folic acid and vitamin B_{12} contents of fish liver extracts and enzymic hydrolysates were comparable with those of beef and pork liver extracts and enzymic hydrolysates. In other B complex vitamins they were lower, especially the extracts. Enzymic digestion gave better yields than extraction, and the dried hydrolysates, unlike the dried extracts, were not hygroscopic. Salmon liver products were particularly good, and the low oil content of salmon liver permits removal of oil and enzymic digestion in one operation instead of two.

It is concluded that satisfactory extracts and hydrolysates can be prepared from fish liver, suitable for use in nutrition or medicine. Pilot plant experiments have begun, but a study of market possibilities is required before it can be decided whether the processes are economic.
